At the Retreat we only use narcotics when ordinary measures have long been persevered with and have failed. It is only fair to say that in some exceptional cases great benefit has seemed to follow. Sometimes the intensity of mental suffering calls for immediate relief, even if only temporary. The problem is to find out the value and the limitations of sedative drugs. I think that members of our association could investigate this problem to good purpose. Our patients live under very uniform conditions; in the nursing staff we have trained observers, and the inquiries could be conducted on a sufficiently large scale to eliminate many disturbing factors. At the outset it would seem advisable to limit the inquiry to groups of cases in which psychical factors in ætiology are of secondary importance, such as acute delirium, the nocturnal excitement in senile insanity, or the agitated melancholia of the climacteric. Two such groups might be compared, one taking no drug, the other any drug that might be selected. I am sure that results thus obtained would be of greater value than the individual opinions of even the most observant people.

#### *The Drink Question.*

Another problem which confronted physicians at the beginning of the nineteenth century is still painfully present with us. It is the alcohol problem. The wastage from intemperance is incalculable, yet we face increasing industrial competition with nations such as the United States, which are relatively abstemious. The word inebriate is unfortunate, as it suggests actual drunkenness, whereas there may be dangerous alcoholic addiction without gross signs of intemperance. This morbid condition, of course, is essentially the concern of psychiatry. It is virtually a disease, although when the exciting cause is removed no symptoms may be discovered.

Experience tells us that the potential inebriate should be treated early, or there will be no hope of preventing confirmed addiction. But the Inebriate Acts are practically useless in the first stages of the disorder. If early treatment is to be obtained it must clearly be on a voluntary basis and in strict privacy, for no one can afford to be branded as an alcoholic.

If the suggestion of Mr. Theodore Neild, of Leominster, were adopted, and a consultation bureau were established in every large centre, much might be done.

#### *Clinics for Early Treatment of Mental Cases.*

But inebriety and drug addiction should not be considered apart from other forms of mental instability. The legislature is taking up the subject of the establishment of clinics or hospitals which will provide early treatment for unconfirmed mental trouble; and the proposed consultation bureaux might be affiliated with these new clinics or form a special department of them.

Unfortunately, many patients decline all treatment and refuse any advice. For these some form of compulsion should be possible. I suggest that any new laws relating to inebriety might provide three separate procedures in dealing with such patients. First, a judicial warning, which might be given privately, when the justice has satisfied himself that the patient is in grave danger of alcoholic or drug addiction. Secondly, if warning and advice failed, the appointment of a guardian, who would be legally authorised to stop supplies, to forbid the sale of liquor to the patients, and to restrict his liberty within prescribed limits. Thirdly, internment in a farm colony or other approved home.

#### *Progress of Psychiatry.*

In comparing the psychiatry of 120 years ago with that of to-day it would be easy to show that progress has been slow

and disappointing. No specific treatment of mental disease has been discovered, save in the case of that arising from thyroid insufficiency; and it is doubtful whether the recovery rate has improved. It is probable that, a century since, the condition of patients in the more enlightened institutions did not greatly differ from their condition to-day.

The medical literature of that period, moreover, contains much that anticipates modern teaching. Haslam, for instance, describes both dementia præcox and general paralysis. The essential mystery of mental disease baffles us now as it did then. Nevertheless, we have achieved a great deal. A vast amount of progress has been made in the anatomy and physiology of the nervous system, in pathology, bio-chemistry, and in many departments of science which intimately affect our subject.

#### *War Neuroses.*

The war has thrown some light upon one aspect of it. We have learned that symptoms formerly termed hysterical or functional are not peculiar to the frail or sensitive, but occur in strong men, that they continue long after any recognised exciting cause has ceased to operate, and that they frequently disappear suddenly as if charmed away. Unfortunately, we cannot analyse the causes of their disappearance, which is ascribed to multifarious agencies, suggestion, psycho-analysis, faith-healing, hypnotism, and ordinary hygienic measures. There is no organic lesion, and the illness, though often accompanied by physical disability, is clearly a disorder of the mind rather than the body. There is urgent need to establish a scientific therapy, that appropriate treatment may be selected with confidence.

We have learned, too, that the functional element in definite organic maladies must not be overlooked. Patients with certain diseases, such as disseminated sclerosis, frequently present symptoms that do not correspond to the extent of the organic lesion.

#### *Conclusions.*

These observations may throw some light on various problems of psychiatry. Do not many of our sudden recoveries correspond to the recoveries in the psychoneuroses? Are not many of our chronic cases akin to that of the confirmed neurotic, with this difference, that in the one, the disordered function affects intelligence and emotion, and in the other some lower nervous mechanism such as vision and muscular coördination? This thought, of course, does not carry us far, but it suggests that the study of hysterical phenomena may help us greatly, and it reminds us to lay due stress on psychical, as well as physical, factors, in the ætiology of mental disease, the attempt to separate mental and bodily factors must inevitably lead to error, since they constantly react on one another.

Be this as it may, we have, at any rate, left behind the doctrine expressed in the dictum: "All insanity is either toxic or traumatic." Just as Tuke and Pinel considered moral treatment of paramount importance in promoting recovery, so we recognise the profound importance of mental strain in the causation and development of certain forms of mental disorder.

#### PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *Mobilised Students and their Medical Studies.*

WAR has left cruel gaps in the student ranks of all professions, especially perhaps of medicine, for all young robust medical students were sent to the very front, whether to the aid-posts or among the squads of stretcher bearers. The survivors are, on account of their age, still mobilised for one or two years, since the term of compulsory service is three years. A large number of older students due for more or less immediate demobilisation are kept, since the armistice, by the Army of Occupation in Germany. The War Minister, at the request of the heads of the medical profession, has repeatedly taken steps to ensure the return of these students and the completion of their term of service in a town with a medical school. In December, 1918, he gave instructions for the recall of all students mobilised 54 months—i.e., already in military service before the war—and of others mobilised 51-53 months who had served

32 months or more in a company of infantry or a squad of stretcher bearers, or had been wounded short of being invalided out. Unfortunately, these limited measures affect only a handful of individual students. The Ministry of War is, in fact, placing great obstacles in the way of their repatriation. A recent decision, ostensibly an improvement on the earlier, introduces only nominal alterations. It adds to the categories already cited medical students of any age posted to other duties than those of the Service de Santé—students, that is, who preferred to enter the infantry, artillery, or air force to making use of their medical training—a very limited number in all. The medical societies and faculties have resolved that all medical students without exception shall be recalled to continue their medical service at some town containing a medical faculty, where they can pursue their studies and still perform garrison duty.

#### *Requisition of Civil Doctors.*

To ensure medical care in regions deprived of doctors by mobilisation the Ministry of War during the two years preceding the armistice had charged with this service mobilised medical men of the later age-groups. These men are now almost all demobilised, and in order to supply their place in localities where the population is scanty or largely indigent the Minister has decided to avail himself of the service of civil volunteers, offering them a monthly stipend of 300 fr., capable of increase in exceptional cases.

#### *Acoustic Troubles in Musicians.*

Dr. Castex has published an intriguing study of the auditory disturbances found in musicians. These are not infrequent, but the author has failed to determine whether the practice of the musician constitutes an actual predisposition in comparison with other occupations. He recognises that the hearing of musicians acquires a special acuity, a fact sufficient perhaps to explain its fragility. Certain musicians, for example, perceive at the same time as the note struck the whole gamut of natural overtones. Among the disturbances noted by M. Castex, some concern the timbre, others the pitch, and others again the intensity of the sound. Sometimes a slight degree of sclerosis only allows of the perception of shrill notes or of the deep tones of the brasses. In other cases there is double audition, the two ears perceiving a different note, the interval between them varying from a semitone to an octave. Others are victims of persistence of the notes, as though the loud pedal of the piano is depressed. Modifications of timbre make the tone metallic or nasal in quality. Painful increase in audition is not uncommon among deaf musicians. They may fall in a faint as a result of intensely loud notes (organ, fanfare of trumpets), when the ear has lost its damping mechanism. The prognosis of these affections depends on the fleeting character or otherwise of the auditory affection, but it is to be noted that incomplete deafness does not prevent a good musician from appreciating the diverse turns and qualities of notes. On the deafness of celebrated musicians, Jean Jacques, Schumann (obsessed by a *fa*), Beethoven himself, it is difficult to express an opinion in the absence of a technical examination, but—and therein is well seen the secondary rôle in music of the sense of hearing—the finest works of the master were written after he had become finally deaf, when (as he wrote himself) “he knew the divine hour in which the composer hears nought but his musical inspirations.”

**DEATH OF THE HON. TARAVETH MADAVAN NAIR, M.D. EDIN.**—Dr. Taraveth Nair, who died in London recently, was prominent in Madras both as a medical man and a political thinker. Educated at the University of Edinburgh, he graduated M.B., C.M., in 1894, and was for some time house surgeon at the Sussex Throat and Ear Hospital, Brighton. In 1896 he proceeded to the M.D. and C.M. degrees of his university, and on his return to India he became a political leader with no little influence. He arrived in London a few weeks ago in a serious condition of health, and succumbed to diabetes, a disease on which as recently as 1914 he had published. This book is a conscientious and careful summary of our present knowledge and theories. In consequence of the frequency of diabetes in India Dr. Nair was of the opinion that organised research into the ætiology and pathology of the disease ought to be conducted in that country on the lines of the anti-tuberculosis campaign in England.

## WOMAN IN INDUSTRY.

(Concluded from p. 169.)

LAST week we summarised the memorandum by Dr. Janet Campbell on the Health of Women in Industry, forming part of the comprehensive Report of the War Cabinet Committee on Women in Industry (Cmd. 135, price 1s. 6d.), dealing then with the effect of industrial employment, first, on the personal health of the woman worker and, secondly, on the function of motherhood. There remains for notice the important section of the memorandum bearing on the means for mitigating the admitted evils, and here, as before, we follow closely the actual words of Dr. Campbell's very clear exposition.

#### IV. SAFEGUARDS AND REMEDIES.

During the war the employment of women has been greatly modified. The number of employed women has increased, they have been employed as substitutes for men in men's work, restrictions with regard to hours have been removed—overtime being general at the beginning of the war and night-shifts usual throughout—and wages have increased to subsistence level in almost all cases and in excess of this in some. The result of these changes on the health of women workers has been summed up in a number of memoranda and reports which have been issued by the Health of Munition Workers Committee. An examination was undertaken by this committee of 2500 munition workers with a view to ascertaining the effects of employment on their health. The actual findings were summed up as follows:—

(1) That there is a definite burden of fatigue which, though relatively small in amount as regards severe fatigue, is considerable as regards that of a less severe character.

(2) That the fatigue and ill-health are less than might have been anticipated, having regard to the hours of work and the nature of the employment, and that this is due, broadly speaking, to the greatly improved attention to the health and welfare of the workers.

(3) That fatigue and sickness are greatest where heavy work is combined with long hours at the factory and associated with onerous domestic duties after factory hours.

(4) That unless brought under control the considerable amount of moderate weariness and ill-health now present is likely to reduce immediate efficiency, and also exercise, in many cases, an injurious effect on subsequent health and on capacity for maternity.

Dr. Campbell's comment on these findings is as follows:—

“The fact that the women were able to stand the work as well as they did was attributed (a) to good wages, enabling them to feed and clothe themselves properly; (b) to healthy conditions in the factories; and (c) to welfare and health supervision, including the provision of protective clothing, canteens, rest-rooms, surgeries and medical advice. It may confidently be asserted that if similar demands had been made upon women working under pre-war factory conditions they could not have been met to the same extent, if, indeed, they were met at all, without causing an immensely greater amount of fatigue and permanent injury to the health of women and girl workers. As it was, most women enjoyed the more interesting, active and arduous occupations, and in many cases their health improved rather than deteriorated. Medical officers of factories and welfare supervisors have pointed out the beneficial effects of open-air conditions (yard work, trucking in filling factories, &c.) on the general health, and the success with which properly selected women have undertaken work involving the lifting of weights, heavy machine work, and even forge and foundry work, without untoward physical consequences. The whole experience tends to show that light sedentary work is not by any means always the most suitable for women, that operations involving a change of posture are preferable, and that, given adequate nutrition, many women would have better health and greater physical vigour if they followed more active occupations.”

#### *Restrictions on Women's Labour.*

The question of restrictions on women's labour then claims attention. The Health of Munition Workers Committee examined a number of witnesses on this point.

Various of these witnesses, Dr. Campbell tells us, urged the abolition of all special protective legislation for women after

the war. They consider that women ought not to be prevented on physical grounds from entering any trades open to men (unless sex injury can be proved, as in the case of lead poisoning), or from working similar hours to men, or from engaging in night-work. It is suggested that the conditions of employment should be improved for men and women equally and that it is unfair to handicap a woman economically by restricting the conditions under which she may work. There is some truth in these arguments, but, on the other hand, it should be remembered that women as a class are still, unfortunately, unorganised and therefore in a far more helpless position than men in the face of unreasonable demands on the part of unscrupulous employers; to abandon all restrictive legislation might still lead to the exploiting of women and the return of some of the abuses which this legislation was designed to remove. The women factory inspectors examined were unanimous in desiring the re-imposition of some restriction of women's labour, though it was considered that a revision of the Factory Acts was desirable.

#### *Shorter Hours.*

The general opinion of the witnesses examined appeared to be that a 44-hour week was advisable for women, with a Saturday half-holiday. Attention was called to the advantage of a short break in the morning spell, especially when work begins early and where there is no breakfast interval, as workers often have no time for a proper meal before leaving home. In the Report of the Chief Inspector of Factories and Workshops for 1917, which Dr. Campbell quotes, Mr. Bellhouse discusses the advisability of commencing work after instead of before breakfast, and sets out the following results of the experiment at Paisley, which are typical of the findings elsewhere:—

(1) Bad time-keeping in the morning has almost disappeared.

(2) Sickness amongst the girls in the first hours of the morning, which was common when work started at 6 A.M., has largely ceased.

(3) Reduction in output is hardly noticeable in departments where it depends on the activity of the worker, and not in proportion to the drop of one hour per day, even in departments where output depends chiefly upon machine hours.

(4) Better work is secured and maintained.

The conclusion drawn is the eminently reasonable one that shorter hours would result in better time-keeping, especially where married women are concerned, and that in most trades and processes output would not suffer and might even improve.

#### *Night Work.*

Night-work, also, comes in for its share of condemnation in Dr. Campbell's memorandum. The conclusion arrived at from the examination of competent witnesses was that it should not be permitted to women after the war, and, in the case of men, it might also be injurious and should never be resorted to except in case of necessity. Night-shifts, and especially permanent night-shifts, Miss Martindale pointed out, were particularly harmful to women with domestic responsibilities, as it was more difficult for them to obtain adequate sleep; they invariably did their own house work during the day and their rest was subject to continued interruption; their work became inferior in quality and their health suffered. Evidence showed that overtime had an injurious effect on workers, and, if continued for a long period, reduced rather than increased the output. It was particularly injurious to girls of 14 to 16 years of age and to women between 30 and 40.

Although some regulation of women's labour is thus likely to be continued after the war, Dr. Campbell foresees the time when the need for special protection for women and girls will disappear in large measure, a revision of the existing Factory Acts leading to a levelling-up of the conditions under which men work to the standard which is now considered desirable for women.

#### *Medical Supervision.*

The whole position in regard to medical supervision is then surveyed. Provision for medical inspection and supervision has already been made by the local education authority for persons up to 18 years of age. It is presumed that every boy and girl will have been under regular medical care and supervision during the whole of school life and will have received treatment for such physical defects as have revealed

themselves. With regard to industrial workers direct supervision was almost non-existent before the war. Experience of war conditions has emphasised the need for more effective supervision and for energetic research into the causes of industrial fatigue and the methods of preventing disease directly or indirectly due to occupation. Factory hygiene must, indeed, become an integral part of the general system of preventive medicine, which is likely to be the most important branch of medicine of the future. For this purpose an adequate service of factory medical officers is needed, having no duties of treatment, but charged with the general oversight of factory conditions, hygiene, and health. With this may be associated the "welfare" service in individual factories, responsible to the factory management, and partly occupied in carrying out recommendations made in regard to the health of the workers.

The duties of the factory medical officers, as sketched out in the memorandum, comprise the supervision of (a) the general hygiene of the factory, including sanitation, ventilation, lighting, heating, &c.; (b) the particular hygiene of processes likely to involve hazard, discomfort, or injury to workers; (c) the maintenance of surgeries, first-aid equipment, rest-rooms, &c.; and (d) the general health and welfare of the workers, men, women, and young people, with particular regard to the conditions under which women and young people are employed. Further, it should be the duty of the factory doctors to investigate and report upon any trades, processes, or forms of work which appear to lead to general or specific ill-health or to shorten unduly the lives of workers employed therein. They should act in an advisory capacity only, and should not undertake the treatment of disease in any form.

As to the administration of factory supervision Dr.

Campbell writes:—

"Such a service might conceivably be established centrally under the Home Office, and locally under the sanitary authority. This would presumably entail the formation of a strong central Medical Department at the Home Office, staffed by men and women doctors, and the appointment of a considerable number of medical officers (women as well as men) to act as local medical inspectors of factories. The nucleus of such a service might possibly be drawn from the ranks of the certifying factory surgeons, whose present duties would obviously be superseded in one direction by the school medical officers, and in the other by the factory medical inspectors. The suggested means of providing for the medical inspection of factories would make it necessary to enlarge the powers and duties of the medical officer of health in connexion with factories and to provide him with a sufficient staff to undertake their adequate inspection and supervision, this branch of his work being under the general control of the Home Office in much the same way as the medical officer of health in his capacity of school medical officer is under the supervision of the Board of Education. Such an arrangement would have the obvious advantage of combining in one local administration the whole of the powers and duties relating to health in any one area, of preventing overlapping of function, and of promoting smooth and rapid action."

Concerning ante-natal and post-natal employment, such evidence as there is suggests that suitable employment under reasonably good conditions is beneficial rather than harmful. As the result of an investigation undertaken by the Women's Industrial Council into the "quality of maternity" in relation to industrial occupation, it was stated that there was practically nothing to choose in quality of maternity between those who went to work and those who stayed at home. Medical witnesses agreed that light factory work was not in itself objectionable, and that it was better for a woman to work than to be under-fed.

For the sake of the mother and the child it is clearly desirable, the Memorandum states, that the mother should have not less than one month of ease and comfort in order to complete her own recovery, and that she should be in a position to nurse her child for the normal period. No extension of Section 61 of the Factory and Workshop Act of 1901 will in itself secure this unless at the same time financial assistance is given to the mother to enable her to remain at home without anxiety.

#### *Grants in Aid of Maternal and Infant Welfare.*

In order that women might be enabled to refrain from work at least sufficiently long after their confinements as to ensure

the proper care of their infants, it was suggested, in the evidence taken by the Health of Munition Workers Committee, that the desired end could be reached by means of adequate grants in aid made to the mother at the time of and subsequent to her confinement. It was the general opinion that these grants should be non-contributory, that they should be available for all women below the income-tax limit (some witnesses preferred to impose no limit), that they should preferably cover a period of nine months after confinement and perhaps one or two months before, but if the cost of this was prohibitive, that they should be for periods of six or three months after confinement, the three months after being regarded as the most vital period. It was recommended that a mother in receipt of grants should be prohibited from seeking employment away from home.

The probable expenditure involved in several alternative schemes was estimated. If grants were given it was considered that they should be available for all women now entitled to maternity benefit, and to these should be added the wives of men who were excepted from insurance under the Act, as there would be no logical reason for excluding them, and their need was often great. This would cost the Exchequer between 5 and 6 millions a year if the benefit was available for a period of six weeks, and between 11 and 13 millions a year if it was available for 13 weeks. It should not be forgotten that these grants would necessarily be supplementary to the existing benefits under the National Insurance Act.

The specific objects of the proposed grants would be, in Dr. Campbell's words:—

(a) To ensure efficient midwifery and nursing at the time of the confinement, and thus to prevent avoidable injury to the mother's own health or to the infant.

(b) To enable the mother to secure adequate nutrition and to obtain the period of rest necessary for complete recovery after confinement.

(c) To reduce infant mortality by ensuring as far as possible regular breast-feeding and the personal care of the mother.

The Memorandum does not rashly assume that the grants would have these desirable effects. If the professional fee were increased it does not follow that more efficient treatment would be obtained, and money spent on the untrained nurse or handy-woman is useless if the intention of the grant is to ensure skilled nursing. It is also doubtful whether grants would make a substantial difference on the infant mortality rate apart from improvements in domestic hygiene, housing, and environment.

What actual difficulties might arise in practice the Memorandum frankly discusses, and with a transcript of these passages we close our survey:—

"The administration of such grants would be difficult and costly. At present there is no machinery for this purpose, though a nucleus might be found in the staff of the local sanitary authority. Presumably the grants would depend on the continued breast-feeding of the infants, a matter not easy to prove. Visits of inspectors (possibly health visitors) to the home, or of the mother to the maternity or infant welfare centres would be necessary, but even so, little control could be exercised over the spending of the money, especially in the later months. If the grants covered a period of six months or longer no mother could be expected to spend the money on herself or on her own food, it would almost necessarily be merged into the family income. The family, as a whole, would gain in consequence, but though this would be a valuable result as far as it went, it would not be fulfilling the express purpose of the grants and might be obtained more satisfactorily in other ways.

"On the whole, the precise effect it is desired to obtain would either not be obtained or would be obtained only in part, while the cost of the improvement made in maternal health and infant welfare would probably be out of all proportion to the results.

"The main criticisms in regard to maternity benefit are that it is an *ad hoc* unsupervised grant, entirely unrelated to municipal provision for maternal welfare and not available for a certain number of women who are perhaps particularly in need of it. Further, it is administered under the Insurance Act by Approved Societies and not by the sanitary authority. Instead of setting up a new system of maternity grants overlapping the existing maternity benefit and administered by another Department of State, maternity

benefit should be transferred to the sanitary authority; it should be placed on a non-contributory basis, made available for all women under the income-tax limit and increased to at least the 60s. now paid to the employed wives of insured men.

"It is idle to expect much improvement in the professional care of the mother and child until we have wholly efficient medical and midwifery services, in addition to a more just and equitable distribution of maternity benefit. Such services could only be organised under a competent health authority. It is essential that the mother should be able to secure a doctor or midwife, whichever she prefers, whose qualifications in this respect are beyond dispute. Further, there should be a full exercise by the sanitary authority of the powers which already exist for the provision of food and milk, advice and treatment for mother and child, health supervision, &c., and their extension as and when found necessary.

"It is submitted that the provision of large grants in aid, with no assurance that they will be applied to the specific purposes for which they were awarded, is an unscientific method of dealing with the problem of maternal and infant welfare, and that in any case to give such grants before securing an adequate health and medical service is unsound administration. If grants or pensions in addition to a revised maternity benefit prove to be necessary, it would be suitable to entrust the administration of such grants to the central and local health authorities responsible for the public health service."

In this short account of the Memorandum many interesting and instructive details have had to be omitted. Anyone interested in the subject would be well repaid for the time spent in the perusal of the whole Memorandum—indeed, of the whole Report.

## URBAN VITAL STATISTICS.

(Week ended July 26th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 10.0, 10.1, and 9.0 in the three preceding weeks, rose to 10.3 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 10.5, or 1.3 per 1000 above that recorded in the previous week, while among the remaining towns it ranged from 3.0 in Swindon, 3.8 in Gloucester, and 4.4 in Lincoln, to 15.1 in Bootle and in Bury, 15.5 in Darlington, and 19.7 in Carlisle. The principal epidemic diseases caused 134 deaths, which corresponded to an annual rate of 0.4 per 1000, and included 54 from infantile diarrhoea, 33 from diphtheria, 22 from measles, 12 from whooping-cough, 11 from scarlet fever, and 2 from enteric fever. Measles caused a death-rate of 1.2 in Newcastle-on-Tyne, 1.6 in West Bromwich, and 2.2 in Barnsley. There were 2 cases of small-pox, 1526 of scarlet fever, and 1140 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 5, 1438, and 1100 respectively at the end of the previous week. The causes of 21 deaths in the 96 towns were uncertified, of which 5 were registered in Birmingham, 4 in Gateshead, and 2 in Liverpool.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 9.9, 11.0, and 10.6 in the three preceding weeks, rose to 11.1 per 1000. The 222 deaths in Glasgow corresponded to an annual rate of 10.3 per 1000, and included 5 from whooping-cough, 4 from measles, and 2 from infantile diarrhoea. The 82 deaths in Edinburgh were equal to a rate of 12.7 per 1000, and included 3 from diphtheria, 2 from measles, and 1 from infantile diarrhoea.

*Irish Towns.*—The 89 deaths in Dublin corresponded to an annual rate of 11.5, or 2.5 per 1000 above that recorded in the previous week, and included 2 each from diphtheria and infantile diarrhoea. The 92 deaths in Belfast were equal to a rate of 12.0 per 1000, and included 2 from scarlet fever and 1 from infantile diarrhoea.

**NATIONAL LEAGUE FOR HEALTH, MATERNITY AND CHILD WELFARE.**—The following resolution was passed unanimously by the League at its last meeting:—

"That this League calls upon the Government to continue some reasonable control of the liquor traffic in the interest of the health and welfare of the mothers and infants of the nation."

The National Association for the Prevention of Infant Mortality, a constituent section of the League, has passed a resolution dealing with the milk-supply:—

"That this Association calls the attention of the Government to the urgent necessity for reconstruction of the milk-supply throughout the country, with regard to (1) its greater purity, (2) freedom from infection, and (3) its seriously diminishing volume. This Association would remind the Government that both the quality and quantity of the milk-supply of the United Kingdom are at present in a deplorable state, and that the earliest attention to the problem is vital to the babies and children of to-day, who will bear the burden of Empire in the future."

## Correspondence.

"Audi alteram partem."

THE COÖRDINATION OF CLINICAL RESEARCH:  
THE POSITION OF PSYCHIATRY.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 21st a letter appeared from me under the above heading, in the course of which I expressed the view that the time was ripe for a conference between local authorities responsible for the care of the insane, the governing authorities of the local university, and of the infirmary, and representatives of the Board of Control, with a view to the establishment of a clinic in psychiatry. Since that date such a conference has taken place in Cardiff, at which the main features of the proposed amending Bill to the Lunacy Laws (which will allow of treatment in early cases of insanity without orders and certificates—in fact, will permit of the establishment of these clinics) were outlined, and the lines upon which the clinic could best be developed in Cardiff were sketched. I understand that similar conferences have been held at Newcastle and at Oxford, and I believe will be held at other university centres. The proposed amending Bill has not yet been adopted by the Government. It may be expected that the proposition will be that the Government should find, say, 50 per cent. of the cost of maintenance, and perhaps as much of the annual charges for liquidation of the capital expenditure, the local authority finding the balance. The answer to the question, Who is to find the money for site and erection of the buildings? is not forthcoming that I know of. I cite from the *Western Mail* of July 18th as follows, in regard to the Cardiff conference:—

The conference was unanimous in the view that a clinic in psychiatry was absolutely necessary, alike in the interests of all sections of the community, and of teaching; and it was resolved that a committee of the authorities represented be formed, to act with the advice and coöperation of the Board of Control, to promote the object in view.

It is obvious that the development above outlined is one of the first importance to the community at large, aiming, as it does, at the prevention of what is probably the most terrible of the ills to which the flesh is heir. In the erection of these clinics, each locality concerned must, in the main, bear its own burden; and there is, therefore, scope for the exercise of that spirit of munificence on the part of private individuals which has never failed to manifest itself in South Wales when an appeal has been made on behalf of suffering humanity.

Some account in due course will be given of the experience gained in treating some 1700 cases of mental disorder amongst troops at the Cardiff City Mental Hospital in its capacity as the Welsh Metropolitan War Hospital (Mental Division). These cases have been admitted and detained on the authority of Army Council Instructions ("for observation and disposal"), but without any orders or certificates or formalities of any kind. I wish I could convey some idea of the gratitude and relief which the relatives of these men have experienced and expressed for this blessed immunity. Yet very large numbers of these patients, had they not been serving soldiers, would have been placed under orders and certificates and have gone through the channel of the Poor-law. Allow me the following citation from a letter just received from a distinguished American psychiatrist, to whom I complained of the woeful backwardness of this country in psychiatry:—

"Perhaps, as a native of England, I may agree with you, without offending taste, that British psychiatry is behind the times in many respects. The Phipps Clinic at Johns Hopkins and the Psychiatric Hospital in Boston have both been stimulating factors in advance, not to mention several other like institutions."

Are we to understand that this (still great) country will continue, either through poverty of ideals or poverty of purse, or both, to remain passive in this matter, and recognise no obligation as a State in regard to the actual finding of money for the erection of these clinics, but relegate this responsibility to the local authority, or trust to the generosity of those to whom the war has brought wealth? I fear the amending Bill referred to will not be dealt with by the Government this year unless it judges the force of opinion to be such that to ignore it would be inexpedient.

I am, Sir, yours faithfully,

EDWIN GOODALL.

Cardiff City Mental Hospital, Cardiff, July 26th, 1919.

NATIONAL HEALTH INSURANCE AND THE  
MEDICAL GUILD.

To the Editor of THE LANCET.

SIR,—Dr. Frederick Porter's letter in your issue of to-day, containing the suggestions of the Scottish Medical Guild with regard to National Health Insurance, is a timely one. The hulk of non-panel practitioners are determined not to sell their freedom by entering into contractual relations with Insurance Committees. They consider that their fees, their times and methods of attendance, and so on, are private matters for mutual arrangement between themselves and their individual patients, and that at any time, if the patient or doctor be dissatisfied, either party should be able to bring the professional relationship to an end at once, without any recriminations or charges one against the other. It is this freedom of choice and power to change which gives adequate protection to the interests of both parties. The question of the *freedom* of the medical profession and the public in their mutual relations is the *root* issue in this matter.

The scandal to which Dr. Porter alludes in the latter part of his letter should certainly be brought to an end. It is grossly unfair that insured persons, who in large numbers prefer and are prepared to pay for private medical attendance, should in effect be subjected to a money fine which is distributed gratuitously amongst panel practitioners who have done nothing to earn it. Another way of bringing this scandal to an end would be to permit every insured person who preferred obtaining and paying for medical attendance himself to *renounce altogether* the "medical benefit" portion of the Act, and in consideration of the money loss thereby incurred by him to have his "sickness benefit" (i.e., sick pay while he is prevented by illness from following his occupation) *proportionately increased*.

It is this sick pay that is the most useful and desirable part of the Act for many insured persons. Those who preferred to continue obtaining "medical benefit" on the panel system would, of course, be free to do so, and their sick pay would remain as before.

I am, Sir, yours faithfully,

Hampstead, N.W., July 26th, 1919.

HENRY SHARMAN.

THE ORIGIN OF LIFE: THE WORK OF THE  
LATE CHARLTON BASTIAN.

To the Editor of THE LANCET.

SIR,—Taking note of a letter, published in your issue of May 29th, from the son of the late Dr. H. Charlton Bastian, and of another in the same number from Sir Ronald Ross, referring to the brave battle for the proper discussion of the question of spontaneous generation carried on all his life by Dr. Bastian, I venture to add my tribute to his memory in appreciation of that long life of persistence in the advocacy of a conviction at variance with that of the scientific men of his day.

In the flush of a newly born activity in the field of biology, in the rise of the great science of bacteriology, the illogical deductions made from the facts set forth by Pasteur and Tyndall passed current as a valid and conclusive negation of the reality of abiogenesis. But according to the professions of modern methods in science you can affirm a fact by demonstration, but to deny and disprove an asserted fact is a very different proposition. Pasteur and his followers proved to the hilt that they could destroy life in certain fluids and prevent its resurrection, but that this disproved the possibility of the birth of life in any kind of media in any combination of chemical elements by no means followed. Yet bacteriologists behaved for a generation after Pasteur as though he and his followers had established this position. In the last one or two decades a change has set in and very few men of science make any such claims; a very large number cannot accept the continuity of cosmic processes as proven unless they accept the birth of the organic from the non-organic and the birth of life from the lifeless.

Dr. Bastian some years before his death sent me some salts and solutions, which, combined according to his directions, examined microscopically and by culture to my satisfaction and sterilised by heat under pressure in closed tubes, exhibited after varying periods of time various forms indistinguishable under the microscope from spores and

bacilli. These were not present before the tubes were sealed. They took various stains, some not so deeply, but on the whole offering little ground for discrimination between them and bacteria. They, however, with the culture media at the command of a fairly well-equipped laboratory presented no evidence of growth.

I had no explanation to give other than that advanced by Dr. Bastian, but inasmuch as we were unable to get a culture and because the simple chemical constitution of the fluids in which they appeared was not in accord with what I have been accustomed to associate with the manifestations of life, I was unable to agree to Dr. Bastian's conclusion that these were not merely simulacra of life, but life itself.

He had, as I look at it, the best of the argument on orthodox scientific grounds. I could not explain the results, and insufficient as I regarded the evidence to be I could only oppose to it a disbelief founded on a theoretical objection, the commonly accepted view of life as being made up of complex molecules interacting upon one another and on their environment in such a way as to exhibit continuous orderly proliferation which we designate by the term "reproduction." A current number of *Science* (June 27th, 1919, N.S., xlix., 1278) contains a paper by Dr. MacDougal which deals with the nature of these molecules. Incomplete as was Dr. Bastian's own experimental evidence and that of the work carried out under my own supervision by those skilled and of long experience in bacteriological technique, I was, under the circumstances, able to offer only a still more unsatisfactory report. Full reports of the work of myself and colleagues were made to Dr. Bastian, and doubtless his son can find them among his papers. The conception of the chemical composition of living matter is largely hypothetical, and the utilisation of all known culture media and devices was not performed. I consider Dr. Bastian offered to the world sufficient evidence to make further investigation an imperative duty on those having the requisite skill and the opportunity to continue the work. His conclusions have never been answered in a way to reflect credit on men of science. I am, Sir, yours faithfully,

JONATHAN WRIGHT.

Pleasantville, Westchester County, New York, July 7th, 1919.

*To the Editor of THE LANCET.*

SIR,—With reference to the recent letters in your columns on the subject of the Origin of Life, I would like to thank all those who have kindly contributed to the discussion and have themselves repeated certain experiments. It would take up too much of your space to reply in detail to all your correspondents. May I point out, however, that Professor W. D. Halliburton is mistaken in supposing that I am not fully acquainted with most, if not all, of the published reports to which he refers. The whole literature of the subject is very familiar to me, not only on account of my father's work, but because I have always taken an interest in the subject myself, and, I hope, without prejudice. Given a primary creation of living organisms, by whatsoever means this may have been brought about in the long-ago past, we are faced with the difficulty of believing that existing micro-organisms are in every case the lineal descendants thereof. It seems, in fact, not unreasonable to suppose that this same genesis of living matter may be constantly occurring to-day under suitable conditions of radiant energy, temperature, season of the year, and suitable combination of the necessary constituents of protoplasm; though, of course, the earliest stages of such a process would necessarily take place beyond our ken in Nature's laboratory, and would be quite invisible even with the aid of the most powerful microscope now available.

With regard to the negative results of the Hon. H. Onslow's researches, referred to by Professor Halliburton, when he says, "This work settles the question of spontaneous generation (in Dr. Bastian's sense) once and for all," it is a significant fact that my father was quite familiar with such simulacra and pseudo-organisms as are described by Mr. Onslow, Prof. Benjamin Moore, F.R.S., Mr. Sydney G. Paine, and others. He frequently found these and nothing else in whole series of his experimental tubes, and recognised them as such. But he did not find that these pseudo-organisms multiplied under the cover glass or in nutrient media after the manner of bacteria and fungi. Moreover, I suggest that Mr. Onslow kept some of his "white solution" tubes far too long—three years in some cases—before finally opening them

and examining their contents. Is it surprising, therefore, that no living organisms were found, but only dead ones? For bacteria in a non-nutrient medium cannot subsist and flourish indefinitely by living on one another.

On referring again to Mr. Onslow's detailed account of his experiments, as published in *Proceedings of Royal Society (B., vol. xc., p. 266)*, I notice that his "yellow solution" was composed of dilute sodium silicate and pernitrate of iron in addition to the other ingredients as contained in the "white solution." This may very well account for his failure to confirm my father's results as described in "The Origin of Life." Professor Hewlett's results, to which Professor Halliburton also refers, if they did not go so far as to prove the truth of archebiosis, certainly do not disprove it, as he himself says in *Nature* of Jan. 22nd, 1914, p. 579. On the other hand, we have the testimony very largely in favour of my father's doctrines from M. Albert Mary, of Paris, in his letter published in your issue of June 28th.

I am, indeed, grateful for the great amount of time and trouble taken by the various observers who have been good enough to investigate these matters for themselves. In view of the importance of the subject, however, it is sincerely to be hoped that experiments on somewhat more extensive lines may now be carried out and that some of the funds from which we hope so much for scientific research may be devoted to this object, so all-important from many points of view, but particularly so from the point of view of medical science.—I am, Sir, yours faithfully,

W. BASTIAN,

Chesham Bois, Bucks, July 26th. Surgeon Commander, R.N.

EDINBURGH UNIVERSITY ROLL OF HONOUR.

*To the Editor of THE LANCET.*

SIR,—It is proposed to publish a roll of honour and war record of the University of Edinburgh, and a letter asking for information as to war service, promotions, honours, &c., with dates, is being sent to all graduates and to the relatives of the fallen whose addresses are known. The number of medical graduates who have given their lives is large, and it has been found difficult to obtain the addresses of their relatives. Will those interested in the forthcoming publication communicate particulars to the undersigned?

I am, Sir, yours faithfully,

JOHN E. MACKENZIE, Major,

Editor of the Roll of Honour.

University of Edinburgh, July 15th, 1919.

THE REMUNERATION OF MEDICAL MEN  
SERVING ON PENSIONS BOARDS.

*To the Editor of THE LANCET.*

SIR,—In a recent issue of THE LANCET there was a letter stating that the Cheltenham practitioners had held a meeting and formulated the terms under which they were willing to serve on Pensions Boards. The majority of us now serving as members on Pensions Boards feel that the present fee of £1 1s. per session of two and a half hours and often longer is quite inadequate payment for the work done. The cases, especially those of suspected tuberculosis, require most careful examination and consideration. There is a feeling amongst us that a good deal of the clerical work of a non-medical character should be done by a clerk. Every few days more clerical work is thrust upon us, but the fees are not raised, although we now have to spend a good deal of extra time in each case. Many of us are demobilised from the R.A.M.C. and while on the look-out for permanent work we are trying to keep the wolf from the door by doing part-time work. The present remuneration is not enough to meet the increased cost of living.—I am, Sir, yours faithfully,

July 28th, 1919.

MEMBER OF THE BOARD.

ACUTE OEDEMA OF THE FACE DUE TO  
POTASSIUM IODIDE.

*To the Editor of THE LANCET.*

SIR,—The occurrence of acute and marked oedema of the face, arising during a course of treatment by potassium iodide, is, I think, sufficiently rare to be of interest.

The patient, a man aged 65, consulted me on account of attacks of giddiness, from which he had been suffering lately, and he also gave a typical history of attacks of angina. His radial and temporal arteries were considerably thickened, cardiac dullness extended beyond the nipple line, the first

apical sound was prolonged and the second aortic sound accentuated. The urine contained neither albumin nor sugar. The patient was advised as to a limitation of diet, given a prescription for (1) some tabella trinitrini, and (2) pot. iod. gr. v., t.d.s. He returned five days later suffering from considerable oedema of both upper and lower eyelids and face. There was no oedema anywhere else in his body, nor was there a history of previous attacks of oedema or a family history of angioneurotic oedema. He also complained of frontal headache and sorethroat. It became necessary to discontinue the iodides, as even with increased doses the symptoms persisted.

Having failed to discover any other cause for this oedema, I believe it to have been due to the administration of the iodides, possibly aggravated by the simultaneous administration of nitrites.—I am, Sir, yours faithfully,

SIDNEY S. LINDSAY, L.R.C.P. Lond., M.R.C.S.

West End Lane, West Hampstead, July 8th, 1919.

## ARMY SURGEONS AND THE F.R.C.S. EXAMINATION.

To the Editor of THE LANCET.

SIR,—Some time ago the Royal College of Surgeons of England announced that "surgeons who hold, or have held, commissions in H.M. Forces during the war and who have done commendable surgical work during such service, may be admitted to the First Examination for the diploma of Fellow on special conditions." It is unnecessary for me to repeat these conditions, as your readers must have seen them. They were also issued to units. Nevertheless I do not think anyone has drawn attention to the anomaly of the conditions or to the unfairness with which they operate. One would have thought that if facilities were to be given at all they would have been in respect of the subject in which special experience might have been gained when on service—viz., operative surgery. That would have been the only legitimate reason for creating short cuts to the F.R.C.S. Even then, the granting of these facilities to a few would not have been fair, because one cannot control one's postings and their resultant opportunities in the Army. The relief provided, however, refers to embryology and physiology—two subjects of which no one by his Army service can have possibly gained any experience. This makes the conditions still more unfair. I submit that if facilities are to be given—and those in respect of ancillary studies difficult for a service man to return to—all who joined voluntarily should be given them. It is quite bad enough that these higher examinations were held at all during the war, thus giving opportunities to the stay-at-homes, but it is worse to reward only some of those who freely and unsparingly gave themselves and jeopardised their prospects.

I am, Sir, yours faithfully,

July 25th, 1919.

LATE R.A.M.C. AND INELIGIBLE.

## THE PAY OF TERRITORIAL MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—I gather that the response of medical men to the War Office appeal for doctors has not been satisfactory. Perhaps the authorities have no idea how bitter still is the feeling among Territorial and Special Reserve medical officers at the difference in treatment recently meted out to them as compared with the temporary R.A.M.C. medical officer. Letters have appeared, representations made, but all to no purpose.

If the War Office were to supplement gratuities of all Territorial and S.R. medical officers (and so compensate them for the monetary loss they have suffered by being a Territorial or S.R. instead of a temporary R.A.M.C. officer), making their gratuities up to a total of, say, £500 for four years' embodied service (the same exactly as a naval medical officer is offered in peace-time after the same length of service, at which rate, too, a regular R.A.M.C. officer's gratuity after eight years' service is calculated), it would help to mitigate some of that soreness still so prevalent. The Territorial and S.R. medical officer is paid at the same rate as the regular: why, then, should not his gratuity be worked out at the same rate—namely, £125 a year for each year of embodied service, or 7s. a day pay? The temporary R.A.M.C. officer gets, after all, the equivalent of this in increased pay daily.—I am, Sir, yours faithfully,

CAPTAIN, R.A.M.C. (T.),  
late Surgeon, R.N.

July 28th, 1919.

## Medical News.

**GRANTS FOR MEDICAL EDUCATION.**—We learn that certain London medical schools, which have prepared schemes for the reconstruction of their clinical teaching, have been officially informed that they can count upon financial assistance from the State based upon the approved expenditure incurred in carrying out those schemes.

**EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.**—At the Final Examination, held from July 1st to 17th, the following candidates were approved in the under-mentioned subjects, but are not eligible for diplomas, viz:—

**Medicine.**—W. J. McB. Allan, Guy's; F. T. Allen, St. Thomas's; H. E. Archer, St. Bart's; S. T. Barrett, B.A. Cantab., Cambridge and Guy's; G. F. Baxter, Westminster; Grace Mary Beaven, L.M.S.S.A., St. George's; Julia Bell, Royal Free and St. Mary's; W. H. Bennett, L.R.C.P. & S. Edin., L.F.P. & S. Glasg., Manchester; P. C. Brett and J. D. M. Cardell, St. Thomas's; Marjorie Carnesw Chapel, Royal Free; B. H. Cole, Cambridge and St. Bart's; Alison Margaret Collie, St. Mary's; K. G. Danie, King's College; Sarah Helen Davies, Royal Free; K. A. Denholm, Queen Univ., Canada; H. Donovan, Birmingham; T. Draper, Edinburgh; A. J. Fenn, King's College; P. C. C. Fenwick, L.M.S.S.A., St. Thomas's; I. Frost, St. Bart's; A. E. Gravelle, L.M.S.S.A., King's College; E. C. Grey, D.Sc. Lond., F.I.C., Guy's; H. M. Guggenheim, M.D. Paris, Paris; H. W. Hardy, L.D.S. Eng., Charing Cross; E. F. Hicks, Cambridge and St. Bart's; T. R. E. Hillier, Middlesex; Mabel Marian Ingram, Royal Free and London; C. A. Kirton, University College; J. V. Landau, St. Bart's; F. G. Lewtas, Cambridge and St. George's; R. T. McKee, London; Margaret Ombler Meek, Cambridge and Charing Cross; G. E. Morgan, Oxford and London; W. P. Newman and C. Nicory, St. Thomas's; Sibyl Gertrude Overton, St. Mary's; G. Packham, L.D.S. Eng., and W. W. Payne, Guy's; J. Posner, Dublin; Eleanor Margaret Reece, Royal Free; H. N. Schapiro, Guy's; Ruth Mary Scutt, St. Mary's; J. T. Short, M.D. Penn., Pennsylvania; J. V. A. Simpson, Middlesex; W. A. M. Smart, B.Sc. Lond., London; H. E. Smith, Sheffield; G. M. Trist, Charing Cross; W. A. Turner, Guy's; G. van Acker, Oxford and Birmingham; A. D. Weedon, Middlesex; Effie Adell Wharton, St. George's; J. S. White, St. Bart's; Octavia Margaret Wilberforce, Royal Free and St. Mary's; Kathleen Mary Wilkinson and Margaret Aileen Williams, Birmingham; T. Williams, Middlesex; W. R. Williams, Liverpool; C. Young, Middlesex; and T. F. Zerolo, St. Bart's.

**Midwifery.**—F. F. Abdullah, St. Mary's; W. G. Bsrnard, London; H. Beger, University College; T. L. Bonar, St. George's; J. Bonfield, M.B. Kingston, Queen's Univ., Ont.; C. H. Bulcock, St. Bart's; G. F. Burnell, Charing Cross; J. W. Chadwick, Manchester; F. Christian, University College; O. T. J. C. de H. Clayre, St. Bart's; G. L. Clements, Birmingham; H. Cohen, Westminster; M. Cohen, Guy's; J. C. Copp, M.B. Tor., Toronto; F. C. Cozens, Cambridge and St. Bart's; A. R. Crane, London; J. J. da Gama Machado, St. Bart's; R. W. M. Dendy, Cambridge and St. George's; K. A. Denholm, M.D. Queen's Univ., Kingston; C. J. C. de Silva, Middlesex; T. Draper, Edinburgh; D. G. Garnett, Cambridge and St. Thomas's; W. Girgis, St. Mary's; A. E. Gravelle, L.M.S.S.A., King's College; E. C. Grey, D.Sc. Lond., F.I.C., Guy's; F. B. Hobbs, Cambridge and St. Thomas's; F. James, Charing Cross; C. E. Kennedy, M.B. Queen's Univ., Kingston; J. V. Landau, St. Bart's; F. F. Langridge, London; T. J. Lesser, Royal Free; H. T. Le Vieux, Guy's; F. C. Lewis, Liverpool; P. T. Liang, Cambridge and St. Thomas's; W. A. Low, St. Thomas's; P. T. McIlroy, M.B. Queen's Univ., Kingston; S. F. Mahmood, St. Bart's; C. G. Martin, Cambridge and St. Bart's; D. J. Millar, M.B. Queen's Univ., Kingston; L. Moss, Guy's; G. G. Newman, London; Olga Grace Mary Payne, M.Sc., M.B., Ch.B. Manch., Manchester; N. A. M. Petersen, London; J. A. M. Ross, St. Bart's; M. Sawhney, Cambridge and Middlesex; J. T. Short, M.D. Penn., Pennsylvania; C. J. Slim, Birmingham; W. A. M. Smart, B.Sc. Lond., London; F. D. Spencer, Birmingham; B. W. Thompson, St. Bart's; B. M. Tonkin, Guy's; D. L. Tucker, Cambridge and Edinburgh; W. G. D. H. Urwick, St. Bart's; G. v. L. van Acker, Oxford and Birmingham; N. V. Wadsworth, Guy's; Mary Howarth Wild, M.B., Ch.B. Liverp., Liverpool; Kathleen Mary Wilkinson and Margaret Aileen Williams, Birmingham; W. R. Williams, Liverpool; Grace Elizabeth Winn, Royal Free and St. Mary's; Jane Edith Wood, Leeds; C. Woode, Charing Cross; and F. B. Yonge, L.D.S. Eng., Middlesex.

**Surgery.**—C. M. Billington, Cambridge and St. Thomas's; M. R. Boe, M.D., C.M., Queen's Univ., Kingston; H. Brockman, Middlesex; G. P. Evans, St. Mary's; L. P. Garrod and N. J. Macdonald, Cambridge and St. Bart's; T. Menase-Annan, Cambridge and King's College; Sibyl Gertrude Overton, St. Mary's; Olga Grace Mary Payne, Manchester; H. W. Pigeon, M.D. C.M. McGill, McGill; R. E. R. Sanderson, Cambridge and St. Bart's; E. R. Sarra, Cambridge and London; Ruth Mary Scutt, St. Mary's; S. D. Sturton, Cambridge and St. Bart's; W. S. R. Thomas, Cambridge and Guy's; R. Thurz, King's College; D. L. Tucker, Cambridge and Edinburgh; Kathleen Suzanne Vine, L.M.S.S.A., Royal Free; W. Walsam, St. Mary's; and M. L. Young, Cambridge and St. Thomas's.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—An ordinary meeting of the Council was held on July 24th, Sir Henry Makins, the President, being in the chair.—The President reported that H.R.H., the Prince of Wales had consented to become an Honorary Fellow of the College. The votes of the Council were taken in accordance with the requirements of the Charter of 1899, and the President declared His Royal Highness to be duly and unanimously elected an Honorary Fellow. The President stated that

the Prince of Wales hoped on his return from Canada towards the end of the year to attend at the College to receive his diploma. The President reported that H.R.H. the Duke of Connaught (Colonel-in-Chief of the R.A.M.C.), had also consented to become an Honorary Fellow of the College. Whereupon the votes of the Council were taken and His Royal Highness was duly and unanimously elected an Honorary Fellow. The Secretary laid before the Council a balance sheet dated June 24th, and a statement of the receipts and expenditure of the College for the year ending on that date, with the certificates of the auditors attached thereto, together with a list of the investments, showing their value on that date. The balance sheet and the statements as to receipts and expenditure were approved and adopted, and it was resolved to publish them in the College calendar and in the annual report of the Council to the Fellows and Members. It was decided that the annual meeting of the Fellows and Members should be held on Thursday, Nov. 27th, at 3 P.M.

**UNIVERSITY OF LONDON.**—At examinations for internal and external students held recently the following candidates were successful:—

#### M.D. EXAMINATION.

*Branch I., Medicine.*—Frank Cyril Harvie Bennett, B.S., St. Mary's Hosp.; Dorah Challis Colebrook, B.S., London School of Medicine for Women; Clement Cooke, B.S., St. Bartholomew's Hosp.; Annie Mary Forster, B.S., London School of Medicine for Women; George Edward Genge-Andrews, B.S., Guy's Hosp.; \*Mary Esther Harding, B.S., London School of Medicine for Women; John Stephen Herbert Lewis, B.S., University College Hosp.; Harold Arundel Moody, B.S., King's College Hosp.; and John Alfred Ryle, B.S. (University medal), Guy's Hosp.

*Branch II., Pathology.*—Graham Selby Wilson, B.S., Charing Cross Hosp.

*Branch III., Mental Diseases.*—Millais Culpin, B.S., London Hosp.; Charles Wesley Forsyth, Victoria University of Manchester and University College Hosp.; and Thomas Chivers Graves, B.S., B.Sc. (Vet. Sci.), University College Hosp.

*Branch IV., Midwifery and Diseases of Women.*—Joseph Anthony Ferrière, B.S., University College; Jerusha Jacob Jhirad, B.S., London School of Medicine for Women; Martin Herbert Oldershaw, B.S., and Victor Jorge E. C. del S. Perez y Marzan, B.S., University College Hosp.; and Cecil George Richardson, B.S., Westminster Hosp.

\* Obtained the number of marks qualifying for the University medal.

#### M.S. EXAMINATION.

*Branch I., Surgery.*—William Bashall Gabriel and Leonard George Phillips, B.Sc., Middlesex Hosp.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

**UNIVERSITY OF OXFORD.**—At examinations held recently for the Diploma in Ophthalmology the following satisfied the examiners:—

Herbert William Archer-Hall, Ernest Milne Eaton, Vernon O'Hea Cussen, Walter Herman Kiep, and William Clark Souter.

**UNIVERSITY OF SHEFFIELD.**—At examinations held recently the following candidates were successful:—

#### M.B., CH.B. DEGREES.

*Final Examination.*—William Collins, Raymond E. Ford, Robert H. Greaves, Dorothy E. Mathews, Reginald E. Pleasance, Frederick Roper, Lazarus Samuels, Frederick L. Smith, and Alice White.

*Third Examination.*—May T. Bassett, Constance M. Chappell, and Raymond E. Ford.

*Second Examination.*—Edgar S. Clayton, Robert Platt, and Elsa F. Paige.

*First Examination.*—George R. Bailey, Oswald H. Billington, Clifford S. Dunbar, Camille Francotte, Rene Francotte, John E. Tannan, William H. Harding (with distinction in Physics), Sidney G. Meanley, James B. Schofield, and Francis A. Wrench.

**LONDON SCHOOL OF TROPICAL MEDICINE.**—The following are the results for the examination held at the end of the sixtieth session (May–July, 1919):—

\*W. B. W. Cheyne (Duncan and Lalaca medals), \*J. I. Connor, \*G. S. Glass, \*R. D. Fitzgerald (Straits Settlements Medical Service), \*Surg. Lieut.-Cmdr. T. C. Patterson, R.N., Capt. W. C. Spackman, I.M.S., P. A. Djal, A. C. Price, Capt. H. N. Stafford, R.A.M.C., J. T. Smeall, Miss Y. H. Hoashoo, Miss S. A. Finch, Miss A. Bransen, N. E. Watch, H. C. Gilmore, S. Fokett, J. W. Scharf, J. P. Tibbles, Miss E. Warren, B. Mountain, B. B. Jareja, C. Farrell, A. R. Neckles, and J. A. Liley.

\* With distinction.

**CENTRAL MIDWIVES BOARD.**—A meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on July 24th, with Sir Francis H. Champneys in the chair. A letter was considered from the medical officer of health for Winchester, inquiring (a) whether the rules of the Board deal with the question of practice by a midwife supposed to be a chronic carrier of disease; (b) whether such a woman, if suspended from practice in order to prevent the spread of infection, would be entitled to compensation from the Board, or from the local supervising authority which has suspended her. The Board directed that the replies be (a) that the question of practice by a midwife liable to be a source of infection is dealt with

in Rule E.6; (b) that by Section 6 (2) of the Midwives Act, 1918, where "a midwife has been suspended from practice in order to prevent the spread of infection the Board, or the local supervising authority by whom she was suspended, may, if they think fit, pay her such reasonable compensation for loss of practice as under the circumstances may seem just."—The secretary tendered his resignation, which was received by the Board with much regret, and it was decided that, subject to the approval of the Ministry of Health, Mr. Herbert George Westley, M.A., LL.B. Cantab., be appointed secretary.

A special meeting was held on the same day when four midwives were struck off the Roll, the following charges, amongst others, having been brought forward:—

A child suffering from inflammation and discharge from the eyes the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E.21 (5). Medical aid having been sought for a child the midwife neglected to notify the local supervising authority thereof, as required by Rule E.22 (1) (a). The midwife not being scrupulously clean in every way, as required by Rule E.2; when attending patients she did not wear a clean dress of washable material that can be boiled, as required by Rule E.2, and when called to a confinement she did not take with her the appliances required by Rule E.3. The midwife did not take and record the pulse and temperature of her patients at each visit, as required by Rule E.14; she did not enter her records of pulse and temperature in a notebook or on a chart carefully preserved, as required by Rule E.14, and she did not keep her register of cases as required by Rule E.24. When called to a confinement the midwife neglected to take with her in a metal case or bag or basket, kept for that purpose only and furnished with a removable lining which can be disinfected, the appliances and antiseptics required by Rule E.3; she neglected to disinfect her hands and forearms before touching the generative organs or their neighbourhood, as required by Rule E.4; she neglected to wash the patient's external parts with soap and water and to swab them with an efficient antiseptic solution, as required by Rule E.8; she neglected to remove soiled linen, placenta, and membranes from the patient's neighbourhood and from the lying-in room before leaving the patient's house, as required by Rule E.11, and she neglected to give the necessary directions for securing the cleanliness, comfort, and proper dieting of the mother and child during the lying-in period, as required by Rule E.12. Medical aid having been sought for a patient the midwife neglected to notify the local supervising authority thereof, as required by Rule E.22 (1) (a). A child suffering from imperforate urethra the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E.21 (5). A patient suffering from rigor with raised temperature, and on subsequent days from other illness, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rules E.20 and 21 (4). A patient suffering from puerperal fever, and the midwife being herself liable to be a source of infection, she neglected to notify the local supervising authority, as required by Rule E.6.

Lieutenant-Colonel J. F. Donegan, R.A.M.C., has been awarded the honorary degree of LL.D. by the National University of Ireland.

Dr. H. Beecher Jackson has been appointed coroner for Croydon.

**SEATON V.A. HOSPITAL.**—This hospital, which was recently closed, was one of the two most economically worked in Devonshire. There was a balance in hand of £1088. £161 were given to the Royal Devon and Exeter Hospital and the balance divided amongst the parishes which had subscribed to the hospital.

**LONDON HOSPITAL MEDICAL COLLEGE.**—A course of clinical lectures for advanced students on "Intermittent Blood Infections and their Relation to Certain Common Diseases of the Kidney, Prostate, Testicle, and other Organs" will be delivered by Mr. Frank Kidd, surgeon in charge of the Genito-Urinary Department, in the Clinical Theatre of the Hospital, on four successive Wednesdays beginning August 6th, at 4.15 P.M. A special course of instruction in the surgical dyspepsias is being repeated on Mondays and Fridays, commencing on August 1st, by Mr. A. J. Walton, assistant surgeon to the hospital. The lectures will be continued till Oct. 27th. Members of the medical profession will be admitted to all these lectures on presentation of their cards.

**LONDON HOSPITAL: AWARD OF PRIZES.**—At a recent meeting of the College Board of the London Hospital the following prizes were presented:—"Price" and entrance scholarships in Science, (£100, £20), Messrs. G. N. Golden, J. A. H. Andre, K. W. Todd (equal, scholarships divided); Epsom scholarship (for students of Epsom College), Mr. G. L. Peskett; prize in Clinical Medicine (£20), Mr. A. B. K. Watkins; prize in Clinical Surgery (£20), Messrs. E. L. Sergeant and A. B. K. Watkins (equal, prize divided); prize in Clinical Obstetrics and Gynaecology (£20), Mr. M. W. B. Bulman; "Duckworth Nelson" prize in Practical Medicine and Surgery (£10), Mr. A. B. K. Watkins; "Letheby" prizes in Elementary Clinical Surgery, Messrs. J. E. Zeitlin, F. H. W. Tozer, and Miss O. G. Potter; "Anderson" prizes in Elementary Clinical Medicine, Miss M. E. Kennedy, Miss D. W. Roughton, Mr. D. C. Williams.

**POST-GRADUATE MEDICAL TEACHING IN GLASGOW.**—Under the joint auspices of the Faculty of Medicine, Glasgow University, and the General Committee for Post-Graduate Medical Teaching in Glasgow a successful emergency course of post-graduate medical study in various institutions in Glasgow has just drawn to a conclusion. The course was arranged to meet the needs of graduates who had been on Service and were returning to take up civilian duties. The facilities offered were taken advantage of by doctors from places as far away as America and China, India and the West Indies, and Basutoland, and while the majority of the graduates who attended the course were officers or ex-officers of the Navy or Army a few local practitioners also availed themselves of the opportunities offered. A further course has been arranged to be held during September and October in Glasgow, and this is to be essentially a practitioners' course. The classes will be clinical and practical, and specially designed to meet the needs of those who have been on Service and are entering or re-entering general practice. In addition to the usual classes in medicine, surgery, and obstetrics a special course on tuberculosis has been arranged at the Consumption Sanatoria, Bridge of Weir, and at the tuberculosis dispensary in Glasgow. In gynaecology and obstetrics exceptional opportunities are available. Special evening demonstrations have been arranged in diseases of the throat, nose, and ear. The syllabus may be obtained from the acting secretary, Dr. A. M. Kennedy, Pathological Institute, Royal Infirmary, Glasgow.

**SOCIÉTÉ DE BIOLOGIE, PARIS.**—Two recent meetings of this society—June 14th and 21st—were devoted to a consideration of the physiology and pathology of aviation. Among the 16 papers read were the following:—

Ferry, A.—Flying Sickness and its Sequelæ.

Elles permettent : 1° De rapprocher des manifestations azotémiques et urémiques de la sclérose rénale, de certains troubles accusés par les aviateurs. 2° De rattacher ces troubles de l'influence surrénale. A. Influence du repos sur la tension sanguine de l'aviateur : il supprime l'hypertension de l'intervalle des vols, réduit l'hypertension consécutive au vol. B. Signes prémonitoires de l'asthénie des aviateurs. C. Rechercher surtout le dédoublement très précoce du 2e bruit, à l'examen du cœur.

Guillain, G., et Ambard, L.—Reaction-time and Flying Aptitude.

La détermination des temps de réaction élémentaire chez les candidats à l'aviation est utile au point de vue documentaire ; mais qu'il ne faut en tirer que des conclusions très prudentes.

Tara.—Blood Pressure Measurements.

Les mesures ont abouti aux résultats suivants : 1° Au fur et à mesure que l'altitude croît, les chiffres des maxima et minima baissent, mais pas aussi vite que la pression atmosphérique. 2° Après grands vols aux hautes altitudes il persiste de l'hypertension surtout aux maxima.

Josue, M. O.—The Airman's Asthenia.

En général la pression maxima est basse. La pression minima est normale. Après repos la pression revient à la normale. Quand on a une maxima très basse et qui se maintient telle, il y a lieu de redouter l'apparition de l'asthénie des aviateurs.

C'est une variété particulière d'insuffisance surrénale. Les signes sont : 1° Asthénie avec perte de la maîtrise de soi, tendance syncopale, quelquefois phénomènes neurasthéniques. 2° Hypotension artérielle portant sur la maxima, quelquefois sur la minima. 3° Ligne blanche surrénale de Sergeant. Durée : un mois 1/2 à 3 mois et plus. Traitement : repos absolu et l'opothérapie surrénale.

## The Services.

### THE HONOURS LIST.

The following awards to medical officers are announced:—

*Bar to Military Cross.*—Capt. F. G. Flood, M.C., R.A.M.C. (Spec. Res.). During operations at Vigozero and Petrovski Yam on March 18th, 1919, he dressed wounded under heavy machine-gun and rifle fire, and under most trying conditions saved many lives. After the action he successfully evacuated all the wounded over 60 versts of most difficult country without losing a case. He showed great gallantry and marked ability and devotion to duty.

*C.B.E.*—Surg. Cdr. R. J. MacKeown, R.N., Surg. Cdr. H. B. Marriott, R.N., Surg. Lt.-Cdr. E. A. G. Wilkinson, R.N., for valuable services in the First Battle Squadron.

### Foreign Decorations.

*Légion d'Honneur (French).*—Officer: Maj.-Gen. M. W. O'Keefe, K.C.M.G.; C.B. Chevalier: Temp. Capt. (acting Maj.) L. D. Woods, R.A.M.C.; Temp. Capt. M. S. Bryce, M.C., R.A.M.C. *Croix de Guerre:* Maj.-Gen. H. N. Thompson, C.B., C.M.G., D.S.O.; Temp. Capt. P. B. Belanger, M.C., R.A.M.C.; Maj. J. M. Bowle, R.A.M.C.; Temp. Capt. (acting Maj.) D. Cowin, R.A.M.C.; Temp. Capt. (acting Maj.) A. R. Green, R.A.M.C.; Temp. Capt. A. A. Greenwood, R.A.M.C.; Capt. (acting Lt.-Col.) H. A. Harbison, M.C., R.A.M.C.; Temp. Capt. (acting Maj.) E. B. Herga, M.C., R.A.M.C.; Maj. (temp. Col.) T. Kay, D.S.O., R.A.M.C.; Maj. B. E. Kelly, Canadian A.M.C.; Temp. Capt. H. Neame, R.A.M.C.; Capt. C. L. Franklin, M.C., R.A.M.C.; Capt. (acting Maj.) N. V. Lothian, M.C., R.A.M.C. *Palme Académique:* Maj. (temp. Lt.-Col.) W. D. C. Kelly, D.S.O., R.A.M.C.; Temp. Capt. (acting Maj.) T. C. Ritchie, O.B.E., R.A.M.C.; Temp. Capt. H. T. Retallack-Moloney, R.A.M.C. *Ordre de l'Etoile Noire:* Maj. (acting Lt.-Col.) T. B. Moriarty, D.S.O., R.A.M.C.

*Order of the Redeemer (Hellenes).*—Chevalier: Temp. Capt. J. Watson R.A.M.C. *Order of George I.*—Officer: Surg.-Cdr. R. C. Sawdy, R.N. *Military Order of Avis (Portuguese)*—Grand officer: Maj.-Gen. H. Carr, C.B., A.M.S.; Maj.-Gen. R. H. S. Sawyer, C.B., C.M.G. (ret. pay), late A.M.S. Commander: Maj. (temp. Lt.-Col.) G. N. Biggs, R.A.M.C.; Lt.-Col. (temp. Col.) J. H. Campbell, D.S.O., R.A.M.C.; Col. H. E. Cree (ret. pay), late A.M.S.; Brev. Col. W. E. Eames, C.B., R.A.M.C.; Col. J. M. Elder, C.M.G., Canadian A.M.C.; Lt.-Col. J. R. Harper, R.A.M.C.; Col. E. M. Hassard, A.M.S.; Col. R. H. Penton, D.S.O., A.M.S.; Lt.-Col. S. J. C. P. Perry, R.A.M.C.; Lt.-Col. (acting Col.) W. L. Steele, C.M.G., R.A.M.C.; Col. H. S. Thurston, C.B., C.M.G., R.A.M.C.; Col. A. H. Waring, D.S.O., R.A.M.C.; Maj. M. C. Wetherell, R.A.M.C. *Cavaleiro:* Temp. Capt. M. du B. Ferguson, R.A.M.C.; Capt. (acting Maj.) A. D. Stirling, D.S.O., R.A.M.C.; Maj. J. L. Wood, R.A.M.C.

*Distinguished Service Medal (Ame. torn).*—Maj.-Gen. (temp. Lt.-Gen.) Sir C. H. Burchell, K.C.B., C.M.G., K.H.S.; Lt.-Gen. Sir T. H. J. C. Goodwin, K.C.B., C.M.G., D.S.O., K.H.S. *Croix de Guerre (Belgian).*—Capt. D. L. Stevenson, M.B.E.

### Mentioned in Despatches.

In a despatch received from the Commander-in-Chief in India the names of the following medical officers and others are mentioned: Maj. F. A. H. Clarke, R.A.M.C.; Capt. F. G. Cross, R.A.M.C.; Maj. A. L. Davies, Hon. Supt. Red Cross D.P., Bombay; Maj. (temp. Lt.-Col.) P. Dwyer, M.C., R.A.M.C.; Maj. W. F. Harvey, I.M.S., Director, Central Research Institute, Kasauli; Maj.-Gen. P. Hehir, C.B., C.M.G., C.I.E., I.M.S.; Lt.-Col. K. V. Kuklay, I.M.S.; Dr. S. K. Millick, C.B.E., Calcutta; Lt.-Gen. Sir T. J. O'Donnell, K.C.I.E., C.B., D.S.O., A.M.S., D.M.S. in India; Dr. S. P. Sarabdhikari, C.I.E., Calcutta; Capt. A. G. Tressider, I.M.S.; Maj. G. S. Wallace, R.A.M.C.; Lt.-Col. H. E. Winter, R.A.M.C.

### Brought to Notice.

The names of Surg.-Lt. E. St. G. S. Goodwin, R.N., and of Surg.-Lt. L. Moss, R.N., have been brought to the notice of the Admiralty for valuable services in the prosecution of the war.

### ROYAL NAVAL MEDICAL SERVICE.

Temp. Surg. Lieut. K. McFadyen, who has been invalided on account of ill-health contracted in the Service, to retain his rank.

To be Surgeon Lieutenants: R. P. Ninnis, E. Heffernan.

Temp. Surg. Lieut. R. A. Brown is transferred to Permanent List of Surgeon Lieutenants.

### ROYAL NAVAL VOLUNTEER RESERVE.

To be temporary Surgeon Lieutenant: E. L. Adendorff.

### ARMY MEDICAL SERVICE.

Col. (temp. Maj.-Gen.) Sir Samuel Hickson, K.B.E., C.B., is granted the honorary rank of Major-General on ceasing to be employed.

Col. Albert L. F. Bate, C.M.G., retires on retired pay.

Col. W. H. Gratton, C.B.E., D.S.O., to be Deputy Director of Hygiene at War Office.

Temp. Col. Sir T. Myles, C.B., relinquishes his commission and retains the rank of Colonel.

### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. J. C. Jameson retires on retired pay.

Major H. W. Farebrother relinquishes the acting rank of Lieutenant-Colonel on reposting.

The undermentioned relinquish the acting rank of Major: Capt. and Brevet Major F. C. Cowtan; Capt. C. Russell, R. A. Hepple, E. B. Marsh, R. Ellis, A. P. O'Connor, N. Cantlie, F. R. H. Mollan; Temp. Capt. C. A. R. McEay, W. C. Douglass, T. Bragg, H. B. D. y. J. S. Doyle, A. P. Saint, J. W. Tocher, J. G. Ackland, A. W. D. Coventon, J. R. Collins, G. Rankine, B. W. Armstrong, H. F. Warwick, A. Leyland Robinson, C. A. Weller, J. E. G. Calverley, A. Poole, T. Kelly, E. G. D. Pineo, A. Felling.

To be acting Majors: Capt. A. L. Stevenson; Temp. Capt. J. Buchanan, W. D. Cruickshank, A. Mathieson, A. K. H. Pollock, D. Cowin, J. V. Grant, T. V. Somerville, E. G. D. Pineo, A. H. Macklin. Capt. F. W. M. Cunningham retires, receiving a gratuity.

Capt. St. J. D. Buxton and H. A. Harbison resign their commissions. To be Captains: Capt. F. K. Tomlinson (from T.F.), H. S. Griffith (from Spec. Res.), K. O'Kelly (from Spec. Res.), T. Young (from Spec. Res.).

To be Temporary Captains: C. L. G. Powell, L. A. J. Graham, W. G. D. McCall, J. M. Ryan.

Captains from Special Reserve to be Lieutenants and to be temporary Captains: D. R. Heunessy, T. Parr, J. D'Arcy Champney, J. W. Hyatt. Temp. Capt. J. K. Holland to be Lieutenant and to be temporary Captain.

Temp. Lieut. T. C. Hughes to be temporary Captain.

Officers relinquishing their commissions: Temp. Lieut.-Col. G. B. Price (retains the rank of Lieutenant-Colonel). Temp. Hon. Lieut.-Col. W. J. Richard (retains the honorary rank of Lieutenant-Colonel). The notification of the relinquishment of the acting rank of Lieutenant-Colonel by Major P. T. C. Davy is cancelled. Temporary Majors retaining the rank of Major: C. D. O. Grange, H. Irving, E. R. Fothergill. Temporary Captains granted the rank of Major: W. K. McIntyre, A. T. Todd, F. J. O. Klug, A. C. Renton, W. H. Bryce, J. H. Legge, R. R. Wallace, T. W. Buckley, R. Millar, J. B. Alexander, G. Rankine, T. Bragg, S. Brown. Temporary Captains retaining rank of Captain: W. A. Wilson-Smith, A. J. D. Cameron, R. Vincent, E. A. O. Travers, O. A. Beaumont, G. C. Wells-Cole, G. H. Urquhart, A. O. Sergeant, W. A. Wheelton, A. Brownlie, D. Kelly, J. Stephenson, J. M. Biggs, M. A. C. Buckell, J. A. Dickson, T. L. Fleming, E. T. C. Hughes, G. F. Hlgden, J. D. Lyle, A. V. Craig, O. J. W. Adamson, F. H. Mosse, J. C. Neil, W. F. Hare, W. P. Philip, P. B. Belanger, M. C. R. Grabame, J. F. C. O'Meara, W. H. Gibson, R. G. Gordon, R. M. Paterson, V. G. Ward, J. Cross, J. G. Lee, P. W. L. Andrew, N. J. Newbould, S. W. Fisk, H. S. Metcalfe, G. W. Pope, W. H. Duncan, P. G. Leeman, P. Ashe, E. O. Marks, C. Garner, C. R. Young, G. Macdonald, A. N. Fell, E. S. Johnson, F. H. Young, H. L. Burton, J. Ross, L. L. Cassidy, A. Vella, T. A. Davidson, F. R. Doughtan, H. T. Retallack-Moloney, T. C. Harte, J. A. H. Teifer, O. R. M. Kelly, C. I. Ilderton, F. V. Hanratty, C. H. G. Gostwyck, R. Lewis, J. F. Venables, T. S. Reeves, H. J. Rawson, J. D. C. Swan, G. B. Charters, J. M. Richey, S. H. Kingston, I. D. Ramsay, H. C. Wert,

M. Gross, J. A. Wood (late temp. Capt., is granted the rank of Captain); Temp. Hon. Capt. D. E. Carter (retains the hon. rank of Captain); Temp. Lieut. O. M. Halsall, W. Hickey, W. E. Thompson, W. Napier, J. E. G. Calverley, E. B. Bate, F. Altken (retain the rank of Lieutenant).

#### Canadian Army Medical Corps.

Temp. Lieut.-Col. (acting Col.) K. St. J. MacDonald relinquishes the acting rank of Colonel.

The undermentioned temporary Majors (acting Lieutenant-Colonels) relinquish the acting rank of Lieutenant-Colonel: S. L. Walker, W. H. Lowry.

The undermentioned temporary Captains (acting Majors) to be temporary Majors: J. H. Slayter, C. T. Wallbridge, C. A. Davies.

Temporary Captains (acting Majors) relinquishing the acting rank of Major: C. B. Kidd, H. B. Van Wyck, R. F. Slater, A. Sterling, H. G. Murray, G. S. Murray, G. S. Gordon, E. P. Lewis, L. F. Jones, D. G. K. Turnbull.

The undermentioned temporary Lieutenants to be temporary Captains: J. E. Wadsworth, M. A. Wittick.

The undermentioned retire in the British Isles: Temp. Major G. J. Gillam; Hon. Major F. Lessore; Temp. Capt. D. G. K. Turnbull, G. J. Preston, A. B. Roberts, R. H. Fisher, R. D. Cowan, A. Keay, G. More; Hon. Capt. F. White.

#### Canadian Army Dental Corps.

Temp. Major (acting Lieut.-Col.) B. L. Neiley to be temporary Lieutenant-Colonel.

The undermentioned retire in the British Isles: Temp. Major L. N. Trudeau; Temp. Capt. W. Kennedy.

#### GENERAL RESERVE OF OFFICERS.

H. A. Harbison and S. J. D. Buxton, late Captains, R.A.M.C., to be Captains.

#### SPECIAL RESERVE OF OFFICERS.

Captains relinquishing the acting rank of Major: H. T. Cbatfield, J. W. Malcolm, T. F. Corkill, F. Cook, J. W. Cannon.

Capt. F. G. Flood, M.C., to be acting Major.

Lieutenants to be Captains: B. G. Derry, J. C. McGregor, J. K. T. Mills.

#### TERRITORIAL FORCE.

Lieut.-Col. (acting Col.) J. Mackinnon, D.S.O., relinquishes the acting rank of Colonel on ceasing to be specially employed.

Major R. B. Purves to be acting Lieutenant-Colonel whilst specially employed.

Capt. (acting Lieut.-Col.) J. Bruce to be Major, and to retain the acting rank of Lieutenant-Colonel.

Captains (acting Lieutenant-Colonels) relinquishing the acting rank of Lieutenant-Colonel on ceasing to be specially employed: P. Moxey, W. B. Keith, T. H. Richmond, T. A. Green.

Captains (acting Majors) relinquishing the acting rank of Major on ceasing to be specially employed: T. C. Britton, A. C. Tibbits, H. Foxton, D. R. Kilpatrick, H. J. Blackler, T. G. Buchanan, G. B. Buchanan.

Capt. (acting Major) A. Leggat relinquishes the acting rank of Major on vacating the appointment as Deputy Assistant Director of Medical Services.

Capt. M. S. Double to be a Deputy Assistant Director of Medical Services, and to be acting Major whilst so employed.

Captains to be acting Majors whilst specially employed: M. Brannan, J. P. Milton, G. Davidson, J. Muir, A. W. Paterson.

2nd Scottish General Hospital: Capt. (acting Major) A. A. S. Skirving relinquishes the acting rank of Major on ceasing to be specially employed.

1st Southern General Hospital: Lieut.-Col. F. W. Ellis is seconded for duty with the 2/1st Southern General Hospital.

2nd Southern General Hospital: Major (Bt. Lieut.-Col.) (acting Lieut.-Col.) A. B. Prowse and Major J. Swain to be Lieutenant-Colonels. Majors (acting Lieut.-Col.) G. Parker and R. G. P. Lansdown relinquish the acting rank of Lieutenant-Colonel on ceasing to be specially employed. Capt. (acting Major) J. L. Firth relinquishes the acting rank of Major on ceasing to be specially employed.

3rd Southern General Hospital: Capt. N. B. Clowes is restored to the establishment.

4th London General Hospital: Major (acting Lieut.-Col.) W. G. Spencer relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed. Capt. (acting Major) C. Gibbs relinquishes the acting rank of Major on ceasing to be specially employed. Capt. W. Turner to be acting Major whilst specially employed.

1st Northern General Hospital: Major T. M. Allison is restored to the establishment.

1st Western General Hospital: Major (acting Lieut.-Col.) R. W. Murray relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

1st London Sanitary Company: Lieut. R. Wood to be Captain.

2nd London Sanitary Company: Lieut. S. G. Reed to be Captain.

#### ROYAL AIR FORCE.

Medical Branch.—Major E. M. W. Hearn (Staff Surgeon, R.N.) relinquishes his commission on ceasing to be employed.

Capt. R. L. Roe to be acting Major whilst employed as Major.

T. C. Backhouse (Captain, A.A.M.C.) is granted a temporary commission as Captain.

The undermentioned are transferred to unemployed list: Major H. Pritchard; Capt. N. R. Williamson, I. L. Waadell; Lieuts. L. C. Broughton-Head, C. H. Vernon, P. E. Williams.

Dental Branch.—Lieut. P. J. Proud is transferred to unemployed list.

## A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

\* No returns.

"Tar" includes all matter insoluble in water but soluble in CS<sub>2</sub>. "Carbonaceous" includes all combustible matter insoluble in water and in CS<sub>2</sub>. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 91b. per acre; (b) 2.56 English tons per sq. mile; (c) 1 g. per sq. metre; (d) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

## Parliamentary Intelligence.

### HOUSE OF LORDS.

MONDAY, JULY 28TH.

#### *Ministry of Health: Consultative Councils.*

On the motion that the House approve of the Ministry of Health (Consultative Councils) Order, 1919, and the Ministry of Health (Welsh Consultative Council) Order, 1919,

Lord DOWNHAM expressed the opinion that the setting up of the proposed four consultative councils was a costly and cumbersome experiment in government, and one which struck at the root of Ministerial responsibility. There was no precedent for it whatever. If the Ministry of Health was to set up these councils with a large amount of machinery, why should not it be permitted to 10 or 12 other great Departments of State also to do so? He wished to know if any estimate had been formed of the cost of setting up these four councils. He moved an amendment to limit the number of councils to two, one for medical services and the other for national health insurance, and to strike out the proposed councils for local health administration and general health questions respectively, on the ground that they were uncalled for, as the Minister could obtain all the advice he required for the numerous bodies who were engaged day by day in the administration of sanitary law.

Viscount SANDHURST (Lord Chamberlain) said he had done his best on a former occasion to show why, in the opinion of the Government, the proposed consultative councils ought to form a most important part of the Ministry of Health Act. He was not prepared with any estimate of the cost, but it was only proposed to have one secretary and one staff, and to use the present health offices. The idea behind these consultative councils was that everything should not be done from Whitehall. The council on the general health question was hardly less important than the other three councils, and he believed the other three to be most important. To make the Ministry of Health Act a success they must endeavour to get the confidence of the people, and having got it, they must enlist the most sympathetic health knowledge and co-operation of all. He submitted that these councils would supply that, and he appealed to the House to support the Orders now before them.

On a division the amendment was lost by 31 votes to 23, and the motion was then agreed to.

### HOUSE OF COMMONS.

WEDNESDAY, JULY 23RD.

#### *Medical Advice for Officers on Leave.*

Colonel YATE asked the Secretary for India whether he was aware of the expenses involved in obtaining medical advice in London for officers on leave from India; and whether he could do anything to assist these officers in that respect.—Mr. MONTAGU replied: All Indian Army officers on sick leave in this country during the war have been admitted to the same medical treatment in hospitals or by private practitioners as British Service officers. Through the generous aid of the London School of Tropical Medicine it has also been possible to arrange to send civil and military officers suffering from tropical diseases to the School hospital at the Albert Docks for diagnosis and preliminary treatment. I hope it may be possible to continue this arrangement. It secures to the officer the best advice on his case and as to its treatment. The hospital charges in these cases are borne by the revenues of India.

#### *Service Disability Pensions.*

Sir B. FALLE asked the Secretary to the Admiralty if he could make any statement as to the service pensions of men invalided, apart from any award in respect of disability.—Dr. MACNAMARA replied: Under present regulations only a man with fourteen years' service is entitled to a life pension on the service disability scale in addition to any award from the Ministry of Pensions in respect of permanent disablement. The whole question of the service disability side of the award made to the men invalided is now being considered.

Sir B. FALLE: Is it on the new basis?—Dr. MACNAMARA: That is the point, whether the service disability side shall be reassessed to an amount proportionate to the new scale basis, but as to that I can give no undertaking at the moment.

#### *Welsh Board of Health.*

Sir DAVID DAVIES asked the Minister of Health when he proposed to appoint the remaining members of the Welsh Board of Health; whether he proposed to give definite powers and duties to the Welsh Board as a corporate body; and whether he would give an assurance that the organisation of his department in Wales would not be proceeded with until the Welsh Board had been fully constituted?—

Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: My right honourable friend cannot yet say how soon any further members will be appointed nor when the whole Board will have been completed. Such powers and duties as may be exercised in Cardiff under Section 5 of the Act will be exercised in manner provided by that Section. The organisation in Cardiff will be developed from time to time in whatever manner the circumstances may render expedient. It would be premature for me to make any forecast in this respect to-day.

THURSDAY, JULY 24TH.

#### *Artificial Limbs for Officers.*

Major COHEN asked the Pensions Minister if he would say whether officers who, as the result of their war service, required to wear artificial appliances were required to bear the cost of repair and renewal of these appliances themselves, although in the case of the sailor or soldier the cost was borne by the State.—Sir L. WORTHINGTON-EVANS replied: I am glad to be able to announce that the cost of repairs and renewals of artificial limbs and other appliances will in future for officers, as for men, be borne by the State. The decision which was some time ago arrived at in regard to artificial limbs has already been announced, and it has now been extended to artificial appliances other than limbs. The serving officer must bear the cost of renewals and repairs until retired, but on his retirement my department will undertake such expenses when necessary from fair wear and tear.

#### *Dental Register in Isle of Man.*

Mr. SEDDON asked the Minister of Health whether he was aware that dental practitioners in the Isle of Man were on a register separate from that of Great Britain; whether he was aware that gentlemen whose names were on the British register could practise in the Isle of Man but not vice versa; and whether the coming amending Bill to The Dentists Act, 1878, would take cognisance of this position and confer the benefit of registration in Great Britain on men on the register of the Isle of Man, in order to give them equal status to gentlemen on the British register.—Commander EYRES-MONSELL (Treasurer of the Household) replied: The Dentists' Register is now common to the United Kingdom and the Isle of Man. By the Isle of Man Dental Act, 1908, provision was also made for a "supplemental register" of persons in practice in the island on Jan. 1st, 1908, and such persons can only practise locally. As regards the latter part of the honourable Member's question it is premature to say what will happen to persons so situated, but the recommendations on the point contained in the Report of the Dentists' Committee suggesting machinery through which claims might be considered will be carefully considered.

MONDAY, JULY 28TH.

#### *Dental Caries in Children.*

Mr. SUGDEN asked the Minister of Health if he would state what steps he was taking to prevent dental caries in children under school attendance age, children in attendance at school, and adults, respectively; and, in view of the prevalence of dental caries, as revealed by recent examinations, in adult males, whether he would issue instructions to local authorities to institute inquiries and forward recommendations thereon for its elimination.—Dr. ADDISON replied: Adequate provision of dental treatment for the whole population as suggested in the honourable Member's question can only properly be produced as an integral part of that complete scheme of national health services which will be amongst the earliest matters to be considered by the Ministry with the advice of the consultative councils. A prime necessity, however, must be certain improvements in the existing arrangements for dentistry suggested in the Report of the Departmental Committee, which will require legislation in certain respects. In the meantime the provision of dental treatment for mothers and children is being developed by several local authorities under the Regulations of the Ministry of Health and by help of its grants; in several school clinics by and of the Board of Education; and in some areas in connexion with Health Insurance. The importance of the matter is emphasised in all suitable communications from the Ministry to local bodies.

#### *Medical Benefit under National Insurance.*

Mr. NEWBOLD asked the Minister of Health if he could state the number of invalided seamen, marines, and soldiers entitled to medical benefit under the National Insurance Acts in England, Scotland, and Wales respectively.—Dr. ADDISON replied: In September, 1917, special arrangements were made as to the provision of medical benefit for men invalided from war services. The approximate number of men admitted to this benefit under these arrangements is 318,000, being 270,000 in England, 28,000 in Scotland, 20,000 in Wales. But there is an additional number of such men who, having commenced to be eligible for medical benefit before September, 1917, are not included in these figures; the number of these is not known, as they are merged in the civil population.

*The Physical Condition of Recruits.*

Major FARQUHARSON asked the Pensions Minister if it was the case that all the scientific data and documents collected by the Ministry of National Service in regard to the physical condition of recruits of His Majesty's Army had now passed into the possession and custody of his department; and, if so, would he forthwith transfer these documents to the Ministry of Health.—Sir JAMES CRAIG (Parliamentary Secretary to the Ministry of Pensions) replied: The whole of the medical and statistical staff of the Ministry of National Service were transferred to the Ministry of Pensions on April 1st last. Part of the staff had been for some time engaged on the work of collating and analysing the scientific data and documents to which the honourable Member refers, and it was considered advisable that they should bring the work with them and complete it. My right honourable friend the Minister of Health has throughout approved of this course of action. It is hoped that the results of this work will be published in the autumn. In the meantime any information is at the service of the Ministry of Health.

*Vaccination in the Royal Navy.*

Mr. JOHN DAVISON asked the First Lord of the Admiralty whether he was aware that Stoker P. O. Arthur Simmons and other men serving on H.M.S. *Culypas* in the Black Sea had been confined to the ship for three months because of their refusal to be vaccinated; whether he was aware that Simmons had already been vaccinated three times whilst in the Navy; whether this punishment was in accordance with the regulations; and whether he would have inquiry made into the matter.—Dr. MACNAMARA (Parliamentary Secretary to the Admiralty) replied: The Admiralty has no information as to the particular case quoted, but the circumstances related in the question are in accordance with the regulations which provide that persons who decline revaccination were not to land in ports where there is danger of contracting small-pox. A virulent type of small-pox is endemic in the Black Sea. The confinement to the ship in such cases is not a punishment, but a necessary precaution to protect both those who decline revaccination and their shipmates.

*Trade Marks and Patent Drugs.*

Sir AUCKLAND GEDDES (President of the Board of Trade), in moving the second reading of the Trade Marks Bill, said that under the first part of the Bill it was intended to have a list or register of trade marks which had Common Law existence. It was proposed to have a part "B" of the register of trade marks, and it would be much easier for anyone who wished to register such marks to get them on to part "B" than on to part "A." The second part of the Bill had very considerable practical importance. There was a great abuse at the present time in connexion with the use of words as trade marks, and it was to deal with that abuse that the second part of the Bill was designed. They had, for example, the case of drugs which in the past were patent drugs. During the period of their existence the name had become the one practical description of them, and when the name became a trade mark they had got a permanent continuation of the patent protection. There was, for instance, among chemical substances the well-known case of aspirin. It was to deal with the difficulties arising from the use of such names as absolutely blocking names upon other manufacturers of the same chemical substance that the second part of the Bill was brought forward. The second reading of the Bill was agreed to.

TUESDAY, JULY 29TH.

*Medical Officers Serving in India.*

Mr. CAPE asked the Secretary of State for War whether Royal Army Medical Corps officers in India who contracted to serve for the duration of the war were being detained whilst other medical officers who only signed yearly contracts were to be demobilised first.—Mr. CHURCHILL replied: Every Regular medical officer of the Royal Army Medical Corps who can possibly be spared has been placed under orders for India so as to release temporary commissioned officers who are serving there.

Mr. CAPE asked the Secretary of State for War whether Regular Royal Army Medical Corps officers were being retained at home stations whilst doctors who took temporary commissions were being detained in India and elsewhere at great personal and financial sacrifice.—Mr. CHURCHILL replied: Officers serving under a yearly contract have been sent home from India, as there is no authority to retain them beyond the period of their contract.

Fleet Surgeon Alfred J. Corrie, R.N., has been elected a governor of St. Bartholomew's Hospital, London.

THE Wellcome Historical Medical Museum will be closed for cleaning and redecoration from August 9th until the end of September.

*Medical Diary for the ensuing Week.***LECTURES, ADDRESSES, DEMONSTRATIONS, &c.**

LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Course of Clinical Lectures for Advanced Students on Intermittent Blood Infections and their Relation to Certain Common Diseases of the Kidney, Prostate, Testicle, and other Organs will be delivered by Mr. F. Kidd:—

WEDNESDAY, August 6th.—4.15 P.M., Lecture I:—Infections of the Kidney: Pyelonephritis and Pyelitis. Clinical Course; Diagnosis; Treatment.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton:—

FRIDAY.—4.30 P.M., Lecture II:—The Clinical History Taking of Surgical Dyspepsias.

*Appointments.*

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

DULBERG, JOSEPH, M.D. Würzburg, L.S.A., has been appointed a Medical Referee under the Workmen's Compensation Act for County Court Circuits Nos. 7 and 8.

EVANS, WILLMOTT H., M.D. Lond., F.R.C.S. Eng., Consulting Surgeon to the Royal Free Hospital.

HIGGINS, T. T., F.R.C.S., Surgeon to the Hospital for Sick Children, Great Ormond-street, W.C.

JAMES, Surgeon-Colonel W. C., M.D., Consulting Physician to the Westminster General Dispensary.

NEWSHOLME, H. P., M.D. Oxon., D.P.H., County Medical Officer of Health, North Riding of Yorkshire.

St. Bartholomew's Hospital and College: BALL, W. G., F.R.C.S., and ROBERTS, J. E. H., M.B., F.R.C.S., Demonstrators of Practical Surgery; WATSON, Sir Charles G., F.R.C.S., Demonstrator of Operative Surgery; DONALDSON, M., M.B., F.R.C.S., Demonstrator of Midwifery; CUNNINGTON, W. A., Demonstrator of Biology;

JOHNSTON, J. H., M.Sc., Demonstrator of Chemistry; HOPWOOD, F. L., D.Sc., Demonstrator of Physics; SHELLSHEAR, J. L., M.B., Ch.M. Sydney, Senior Demonstrator of Anatomy; RAMSAY, R. A., M.C., M.B., GRIFFITHS, H. E., M.B., B.S., and HUME, J. B., M.R.C.S., L.R.C.P., Demonstrators of Anatomy; TREVAN, J. M.B., B.S., Senior Demonstrator of Physiology; DREYER, N. B., and HILTON, R., Demonstrators of Physiology; CANTI, R. G., M.B., B.C., JOEKES, T. M.B., and MURRAY, E. G. D., Demonstrators of Pathology; and SHORE, T. H. G., M.D., B.C., Curator of the Museum.

General Infirmary, Leeds: WATSON, GEORGE W., M.D., F.R.C.P., Honorary Physician; BRAITWAITE, L. R., M.B., Ch.B., F.R.C.S., Surgeon in Charge of Out-patients; LEE, HARRY, M.B., B.C., F.R.C.S., Honorary Ophthalmic Surgeon; BURROW, J. LE F., M.B., Ch.B., Honorary Assistant Physician.

London (Royal Free Hospital) School of Medicine for Women: KEENE, MARY L., M.B., B.S., Lecturer in Anatomy and Head of the Anatomy Department; KEDDEN, J. W., M.B., B.S., ABEL, L., M.B., B.S., HOUNSFIELD, MARY, M.B., B.S., and JOLL, MARY, M.D., B.S., Demonstrators of Anatomy; SPILSBURY, B. H., M.B., Ch.B., Lecturer in Forensic Medicine and Toxicology; SCARBOROUGH, ELEANOR, M.B., B.S., Demonstrator in Pharmacology; ROSS-JOHNSON, M., Nat. Sci. Tripos, Camb., and WOODMAN, D., B.Sc., Demonstrators of Physiology.

Miller General Hospital, Greenwich: JOLL, C. A., M.S., B.Sc. Lond., Surgeon; HINE, M. L., M.D. Lond., F.R.C.S. Eng., Ophthalmic Surgeon.

Victoria Hospital for Children: EVERIDGE, J., F.R.C.S., JOLL, C. A., F.R.C.S., and MARSHALL, C. J., F.R.C.S., Surgeons to Out-patients; GOULDER, C. B., F.R.C.S., Ophthalmic Surgeon; KAY, VAL, L.D.S., Dental Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: R. J. BRUCE, M.B., Ch.B. Aberd. (Turriff); MALONEY, J. A., (Clurehill); DAVIES, H. O., M.B., Ch.B. Glasg. (Nanigaredig); GRIFFITHS, D. H., M.R.C.S., L.R.C.P. Lond. (Cross Hands).

*Vacancies.*

For further information refer to the advertisement columns.

Bedfordshire Education Committee.—School Dentist. £400.

Birmingham City.—Municipal Bacteriologist. £700.

Birmingham Municipal Anti-tuberculosis Centre.—Sen. Asst. Tuberc. O. £600.

Birmingham, Rubery Hill Asylum and Annex at Hollymoor.—Med Supt. £1250.

Brighton, Royal Sussex County Hospital.—Sen. H.S. £140.

Cairo, Egyptian Government School of Medicine.—Professors and Lecturers. ££1000 and ££600. Also Radiologist and Lect. in Radiology, ££500, Anaesthetist and Lect. in Anaesthetics, ££500, and Registrar and Tutor, ££600.

Carmarthen Mental Hospital.—Second Asst. M.O. £250.

Croydon County Borough.—M.O. £400.

Devonport, Royal Albert Hospital.—Res. H.S. £200.

Dorchester, Dorset County Council Education Committee.—School Dentist. £350.

Downpatrick, Down District Asylum.—Asst. M.O. £250.

East Ham County Borough Education Committee.—School Dentist. £400.

Ely, Isle of Ely County Council.—Asst. Tuberc. O., M.O.H., and School M.O. £450.

*Fulham Infirmary, St. Dunstan's-road, W.*—Three Asst. M.O.'s. £350 and £300.  
*George Town Municipality, Penang, Straits Settlements.*—Asst. M.O.H. \$4200.  
*Gravesend Hospital.*—H.S. £270.  
*Great Northern Central Hospital, Holloway, London, N.*—H.P. £150.  
*Home Office, Whitehall, S.W.*—Med. Inspector of Factories. £500.  
*Hong Kong Government.*—Bact. and Path. £500.

*Huddersfield County Borough Education Authority.*—Full-time Dent. Surg. £350.  
*Hull Education Committee.*—Asst. Sch. M.O. £450.  
*Kettering and District General Hospital.*—Res. M.O. £200.  
*Kharloun, Wellcome Tropical Research Laboratories.*—Asst. Bacteriologist. £2E.600.  
*Lancaster County Asylum.*—Temp. Asst. M.O. 7 guineas per week.  
*Leeds Public Dispensary, North-street.*—Res. M.O. £230.  
*Liverpool, Samaritan Hospital for Women, Upper Parliament-street.*—Asst. S.'s.  
*Liverpool School of Tropical Medicine.*—Asst. Lect. in Parasitology. £250.  
*Liverpool University.*—Chair of Anatomy. £800.  
*Macclesfield, Cheshire County Asylum, Parkside.*—Locum Tenens. £7 1s. per week.  
*Maidstone, West Kent General Hospital.*—Jun. H.S. £125.  
*Manchester, Baguley Sanatorium for Tuberculosis.*—First, Second, and Third Asst. M.O.'s. £400, £350, and £300 respectively.  
*Manchester Royal Infirmary.*—H.S.'s. £25 for first six months, £50 for second six months.  
*Newark Hospital and Dispensary.*—Res. H.S.  
*Newcastle-upon-Tyne, University of Durham College of Medicine.*—Demonstrators of Anatomy and Physiology. £350 to £500 and £300.  
*Newport Borough Asylum, Caerleon, Mon.*—Asst. M.O. £300.  
*Northampton County Borough Education Committee.*—Female Asst. School M.O. £350.  
*Nottingham, Notts Education Committee.*—Asst. School M.O. £425.  
*Peckham House, 113, Peckham-road, S.E.*—Sen. Asst. M.O. £400.  
*Poplar Hospital for Accidents, Poplar, E.*—Sen. Res. M.O. £200.  
*Rainhill, near Liverpool, County Asylum.*—Temp. Asst. M.O. 7 gs. p.w.  
*Rochester, Kent, St. Bartholomew's Hospital.*—Jun. Res. M.O. £150.  
*Royal Chest Hospital, City-road, E.C.*—Res. M.O. £200.  
*St. Mary's Hospital Medical School, Paddington, W.*—Lecturer on Chemistry. £300.  
*St. Mary's Hospital for Women and Children, Plaistow, E.*—Dent. S. £50.  
*St. Marylebone Infirmary, Rackham-street, W.*—Third Asst. M.O. £200.  
*Salford Royal Hospital.*—Hon. P. and Hon. Asst. P.  
*Serbtu Hospital.*—Surgeon.  
*Severelles Government.*—Asst. M.O. and Visiting Magistrate. Rs.5000.  
*Sheffield Royal Infirmary.*—Asst. H.P. £150.  
*Taunton, Somerset and Bath Asylum, Colford.*—Asst. M.O. £300.  
*West African Medical Staff.*—Number of appointments. £400.  
*Westminster Hospital, Broad Sanctuary, S.W.*—H.S.  
*Weymouth, Princess Christian Hospital.*—H.S. £200.  
*Wigan Infirmary.*—Jun. H.S. £225.  
*Willesden Urban District Council.*—Asst. M.O.'s. £550 to £650.  
**THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Belth and Crossbills.**

## Births, Marriages, and Deaths.

### BIRTHS.

**ANDERSON.**—On July 23rd, at Yealm Cottage, Loughton, Essex, the wife of Dr. A. W. Anderson, Ogmere Vale, Glam., of a daughter.  
**COWAN.**—On July 24th, at Thetford, the wife of Geoffrey Cowan, M.D., of a daughter.  
**DOWNES.**—On July 22nd, at "Palmers," Great Marlow, Bucks, the wife of Dr. G. E. Downes, of a son.  
**DUNLOP.**—On July 22nd, at Conyers House, Newcastle-upon-Tyne, the wife of E. Craig Dunlop, M.B., B.S., of a daughter.  
**KEMP.**—On July 24th, at Caversham, Lemsford-road, St. Albans, the wife of C. Gordon Kemp, M.D., of a daughter.  
**WILLAN.**—On July 25th, 1919, at 23, Claremont-place, Newcastle-upon-Tyne, to Dorothy (*née* Shawyer), wife of R. J. Willan, M.V.O., F.R.C.S., a daughter.

### MARRIAGES.

**BATTEN-TURNBULL.**—On July 23rd, at Essex Church, Nottingham Gate, W., Captain Lindsey Willett Batten, R.A.M.C., to Ellen Mary, elder daughter of Dr. and Mrs. G. Lindsay Turnbull, of Ladbroke-square, W.  
**EDWARDS-BIRD.**—On June 11th, at All Saints' Church, Srinagar, Kashmir, the Hon. Major-General W. R. Edwards, C.B., C.M.G., K.H.P., I.M.S., Director-General, Indian Medical Service, to Nell, widow of Lieutenant-Colonel R. Bird, C.I.E., M.V.O., I.M.S., and daughter of the late Lieutenant-Colonel R. Dewar, R.A.  
**FARQUHARSON-BANES.**—On July 16th, at the Church of St. Michael and All Angels, Southampton, Donald Charles Farquharson, M.R.C.S., L.R.C.P., to Loveday S. Banes, M.B., B.S. Lond.  
**WOODHOUSE-FERGUSON.**—On July 24th, at St. Peter's, Cranley-gardens, Kensington, Sydney C. Woodhouse, M.B. Lond., M.R.C.S. Eng., Temporary Surgeon Lieutenant, R.N., to Erica, younger daughter of the late Donald and of Mrs. Ferguson, of Croydon, formerly of Colombo, Ceylon.

### DEATHS.

**HUBBARD.**—On July 23rd, in London, Daniel Lovett Hubbard, M.B., B.S., of Bordighera, aged 99 years.  
**POCOCK.**—On July 23rd, at Oxford-gardens, Frederick Ernest Pocock, M.D., M.R.C.S., late of "The Limes," St. Mark's-road, North Kensington, aged 67.  
**READ.**—On July 23rd, at Downshire-hill, Hampstead, Charles Read, M.D. Lond., aged 81.  
**YOUNGER.**—On July 24th, at 2, Mecklenburgh-square, W.C.1, Edward George Younger, M.D., M.R.C.P., aged 69 years.

**N.B.**—A fee of 5s. 4s. charged for the insertion of Notices of Births, Marriages, and Deaths.

### BOOKS, ETC., RECEIVED.

**ARNOLD, EDWARD, London.**  
*Diseases of Women.* By Ten Teachers under the direction of Comyns Berkeley, M.C. Cantab. Pp. 650. 30s.  
**BAILLIÈRE, TINDALL, AND COX, London.**  
*Aids to Ophthalmology.* By N. Bishop Harman, M.B., F.R.C.S. 6th ed. Pp. 226. 3s. 6d.

## Notes, Short Comments, and Answers to Correspondents.

### MUSCLE TRAINING IN RECLAIMING CRIPPLES.

By JAMES PATTERSON, M.D.,

CAPTAIN, CANADIAN ARMY MEDICAL CORPS; OFFICER IN CHARGE, MASSAGE, HYDRO- AND ELECTROTHERAPY, AND REMEDIAL GYMNASIUM, GRANVILLE CANADIAN SPECIAL HOSPITAL, BUXTON, DERBYSHIRE.

THE ideas underlying this paper may be expressed thus: success in restoring function demands a common-sense application of a simple knowledge of physics, anatomy, and psychology. Given that, and sufficient help, muscle training will play an increasingly satisfactory rôle in the reclaiming of crippled men. And the greatest efficiency will be attained under unity of direction. The hydro-therapy, massage, electro-therapy, gymnasium games and remedial workshops must form one department with coördinate effort to that end.

#### *Physical Remedies.*

Heat, whether in the form of the eau courante baths, whirlpool baths, hot packs, or the radiant-heat box, makes possible a greater range of motion, either passively or voluntarily. Next comes massage and passive movement, the application of which is universally conceded to be efficacious. Great care is necessary in applying this remedial agent. It must be done without pain until the operator has the absolute psychic and muscular coöperation of the patients. Then it is possible, and often desirable, to push passive movements to the point of causing distress. But unless this happy coördinate effort between masseur and patient obtains, we find that although the patient may be willing to suffer pain in order to secure movement, the muscles controlling the part affected are in a state of rebellion, the one set acting absolutely independently of his consciousness against the set from which we desire to obtain action. But with massage properly given this muscle terror is entirely overcome.

As to electro-therapy the galvanic current has a use in helping to maintain function in muscles to which the nerve-supply is destroyed. The faradic current has tremendous helpful influence in building up weakened muscles that have been out of use for a period, from any cause whatever, but to which the nerve is intact. And we cannot neglect what may be termed a psychic lameness—that is, a habit of thought that the affected part is not usable.

In muscle training itself two elementary facts must be noted. The first is, we must put the muscle group we are working on in such a position that it does not contend against the force of gravity. The other is that a most useful aid comes by having the patient perform the motion with the good limb that he is being taught to perform with the crippled one.

Our method of attack, then, entails a knowledge of the subjects mentioned. The war has forced on the profession the value of all these physical remedies, and each one has its use, its limit, and its definite place. To secure the best results the hospital should have a department of physical remedies under one head, and with plenty of help, alike of fully trained medical officers, competent masseurs, and remedial instructors. These medical officers and trained assistants must know not only massage, but hydro- and electro-therapy and physical training, because only by the most close coöperation between the workers in these very closely allied lines can we hope to obtain rapid and effective results. The sooner expert treatment of this sort is established the better, thus preventing adhesions forming. However, we must at present deal with the cases that come to us, where there may be more or less firm fixation between muscle planes, tendons, and tendon sheaths, and deformities due to contractures. [A rough ground-plan of a treatment department, suitable to take the cases from a hospital of about 1400 beds, was here put forward, showing a logical arrangement of heat, massage, and electro-therapy.] Continuous with this should be the gymnasium, into which the patient may be at once taken to carry on his treatment, or from which he may be sent after his efforts there. The building should be large enough, light enough, and warm enough to be comfortable, with little and simple apparatus, and plenty of room for games.

#### *Metatarsalgia.*

We now come to some special problems. The first of these forms too large a percentage of disabilities, and is preventable—namely, metatarsalgia. Primarily the term refers to the condition known as Morton's disease, but here we must group not only the metatarsalgias, but also the deformities of the anterior part of the foot, bunions, hammer toes, and law feet. These conditions have, as a most notable contri-

butory cause, the wearing of boots too short and improperly shaped. The hampering of the toes causes a distortion of their joints, particularly a partial luxation of the proximal phalanges on the metatarsals.

For cure we must have first of all boots of the proper size, which is three sizes longer than the foot. The foot being measured for a boot is lifted from the ground. When a person puts his full weight on his foot it spreads antero-posteriorly from one to two shoe lengths, sometimes more. Again, we are placing two curved surfaces together; when the foot bends in the boot it is the inner of the two curved surfaces. The sole of the boot must be sufficiently long to allow of this curving of the foot without distorting the inner curve. A man working in this department must provide himself with a shoemaker's foot measure, and be ready to explain why such a sized boot is worn. A size is three-eighths of an inch. But how much better it would be if each non-commissioned officer in charge of the boot stores had such an instrument and issued proper sized boots to each soldier.

Next to consider is the shape of the boot. It must be wide at the toe to allow the toes to come straight from their respective metatarsal bones, and the cap must be firm and extend sufficiently far back to prevent wrinkling of the upper from pressing on the already deformed toes. Besides that it must have a snug-fitting heel seat, and grasp the waist of the foot firmly, widening forward to allow the metatarsals to spread and the toes to come straight. Given this, a bar put across the sole, as recommended by Sir Robert Jones, is of inestimable value. Other men have used successfully an adhesive strap around the foot, with or without a pad of felt to lift the transverse arch, and Goldthwaite's figure-of-8 strap has its sphere of usefulness. For the more stubborn cases a sandal, cut to allow of the toes assuming their correct position, with a bar behind the metatarsal heads and with adjustable straps or tapes to pull the deformed toes into their proper places, has been most effective.

These things are palliative, and we must not only use them but re-educate the intrinsic muscles of the feet so as to obtain full and strong action at the metatarso-phalangeal joints. The set of drills adopted for this purpose can be drawn up by anyone with a knowledge of the muscles involved. A bar of wood works well, curved to lift the transverse arch, and perforated for a strap or a heavy cord, so that when the patient adjusts this behind the metatarsal heads and pulls on the cord he has a counter force on which to work at obtaining flexion at the metatarsal phalangeal joints. The difficulty that patients tend to flex the inter-phalangeal joints must be overcome by supervision. Other exercises are drills in abduction and adduction of the toes, and here, again, the game idea is the most satisfactory aid. Patients can early begin to pick up marbles and golf balls and regain prehensile power; after that games can be devised.

#### *Flat-foot.*

In flat feet the longitudinal outer arch rarely gives trouble, but the inner, longer, and more springy arch frequently results in casualties, and it is mainly the tarsal bones and the muscles and ligaments that hold them in place with which we have to deal. It is on the tibialis posterior that we mainly depend for cure. The symptoms of flat-foot are numerous, and the examination is not always satisfactory. One gets all the grades from the beginning with only vague pains, to the most pronounced luxation of the tarsus, with marked deformity and absolute rigidity. In the early stages we can be pretty sure of our ground if we keep in mind the position of attachment of the tibialis muscle, its action, and the relief or increase of pain on pressure along it, and along the inner longitudinal arch when we invert or evert the foot. One very characteristic place for pain to be obtained by this manoeuvre is where the belly of the muscle changes to the tendon.

Any of the various methods of treatment succeeded more or less: moulding over a triangular block followed by plaster-of-Paris fixation; plates; alteration of the boots by advancing the inner side of the heel; and raising the inner side of the heel and sole. Relief may also be obtained by use of adhesive plaster strapping and corrected boots. But unless we develop and strengthen the tibialis posterior muscle we do not obtain a permanent cure. The first thing to recognise in weakness of the tibial muscles is the concomitant contracture of their opponents, the peroneals; and with the weakening of the ligaments on the inner side there is a corresponding contracture of the ligaments and fibrous tissues on the outer side of the tarsus. In order to get a coördinate relaxation of the muscles in question it is necessary to re-establish tone in the muscles that have lost their power. One very effective means that we use is having the patients walk on an angled board, the two boards being joined at an angle of 45°. With that we have a series of drills in ankle rocking, also some steps of the sailor's hornpipe. Other dances can be used as strength increases. When one considers the attachments of the muscles one can devise a variety of movements.

It is essential that the patient stand and walk, and do all his exercises with the feet parallel and 5 inches apart. This gives an even pull for all the muscles, and if persisted in will, with other measures, cure any case of acquired flat-foot. The usual position of attention, with the feet at an angle of 45°, gives the peroneal group advantage over the tibial group and tends to produce flat-foot.

#### Internal Derangements of the Knee.

Another special problem is the internal derangements of the knee, of the internal lateral ligaments, and dislocation of the internal semilunar cartilage; they are most unsatisfactory, causing recurring disability to the patient and an enormous loss of time to the army. These injuries always occur as the result of an inward twist to the knee when it is partially flexed and the foot turned out. When we consider the anatomy of the knee-joint it is not strange that the majority of our injuries are to the inner lateral ligaments and the inner semilunar cartilages. It is the weaker part of the joint.

On examining a knee of this sort we observe, whether there be swelling or not, tremendous atrophy of the vastus internus. In the early stages heat and massage play a part in relieving pain and swelling, but perhaps faradic stimulation to the vastus internus is the most important physical remedy in restoring tone. However, unless this electric treatment is followed by muscle training we do not attain our end. With the intelligent co-operation of the patient it is possible to get results without either massage or electrical treatment. A combination of all, however, gives best results.

One of the earliest exercises to develop this muscle may be termed "knee-rolling." This can be done in the early stage when it is not advisable to have the patient bear weight on the joint, by having him sit so that the heel touches the floor, and with the tip of the affected side nearly free from the bench. Here he begins describing circles with the knee, either inward or outward, and the instructor sees that he gets the proper contraction of the vastus internus muscle. The straighter the leg the more action is got in that muscle, but long before he can get complete extension contractions occur.

But knee-rolling is not sufficient in itself. Frequently a lift on the inner side of the heel and sole is of decided advantage. Far beyond the use of this, however, is the insistent observance of the placing of the feet parallel and 5 inches apart in all walking, standing, or drilling. The double knee bend is bad in internal derangement of the knee, and has resulted more than once in dislocation of the semilunar cartilage. The stronger position of the knee with the feet parallel and 5 inches apart over that of the usual position of attention can easily be felt in one's own joints. For these reasons and because of the very notable improvement and not infrequent cures obtained, we consider it essential in all remedial muscle training that patients stand and move with the feet parallel and 5 inches apart. Were this adopted universally in the physical training, both in the army and in schools, it would very much reduce the casualties from sprained knees and also flat feet.

Of great importance is the manner in which the exercises are given. Individual drill is impracticable, so cases are arranged in classes, which will as nearly as possible group similar disabilities. These classes are named from the parts to which most of our effort is directed—i.e., shoulder, elbow, wrist and hand, thigh, leg, foot, back, special, and general or Swedish drill. The leg class includes flat-foot cases. The special class is devoted to cases that do not fit in the others, or need individual attention, and also to stump cases learning to walk on peg legs. To these classes the patient is sent, as his progress in the massage and electro-therapy departments indicates.

Psychic lameness is a tremendous factor. The closer one is to the bed the more simple and gentle must the commands for exercises be in order to restore co-ordinate movement. The reason is obvious. When function has been eliminated for any period of time it takes some mental training before the patient can hope to get any muscular action, consequently the commands given should be given distinctly, and should call for very simple movements. In a hospital where the patients come almost directly from the bed sharp commands and complicated movements have a distinctly deleterious effect, and this is particularly true in neurasthenics, hysterics, and shell shock cases.

When the patient is advanced to a reasonable stage the next step is to introduce him to outdoor games. Any game with a ball seems to take with the Anglo-Saxon, and the element of competition leads to many involuntary efforts, often with surprisingly beneficial results. As soon as possible one must get away from treating the injured part, and make the patient feel that he need no longer focus his attention on his disability. For example, much can be done for upper extremity injuries by skipping-rope dances.

Vocational training has its sphere, but that is not in our province to discuss now. Workshops have a potent part to play. The effectiveness of that part, however, depends on the

creative interest evoked in the patient by the work he chooses, and can in no way be measured by marketable value or usefulness. If the result of the patient's activity be useable or saleable so much the better. That idea can often be instilled to incite interest. The workshops should be equipped simply, with reasonable expenditure, as to material and tools—all hand and foot power—and should offer as varied activities as can be arranged. An effort to combine the treatment shops with splint or hospital requisite factories is futile, a failure either way.

For measuring progress, complicated apparatus is a distinct disadvantage in dealing with large numbers. With the simplest goniometer one can get a very satisfactory idea of progress in the movement of joints. A statement of how far the patient can travel on a Ling beam or parallel bars, or how often he can "chin himself," is an accurate enough index of the strength in arm cases; while a march over a measured route, with notations of where the patients drop out, serves in leg cases. And in order to co-relate the work done in hospitals with later progress a note of weekly examinations should be made by the medical officer in charge of the treatment department—i.e., massage, electro-therapy, and gymnasium—as to improvement or lack of improvement. This record should follow the patient up, so as to save duplication of effort.

#### THE CONVERTED ARMY HUT.

THE Disposal Board of the Ministry of Munitions have erected on the Horse Guards Parade, St. James Park, London, S.W., a 60 ft. x 15 ft. army hut which has been converted into a bungalow. As remodelled, the hut comprises a living-room 20 ft. x 15 ft.; three bedrooms, one 15 ft. x 10 ft., and two others 10 ft. by 10 ft., the height of the rooms being about 7 ft. 9 in. There are also a scullery, larder, bath, w.c., and coal house. The hut is lined with asbestos filled in with coke breeze. A cooking range, stoves for the bedrooms, and an 18-gallon farm boiler are provided. The price of the hut unconverted is £100, the cost of turning it into a dwelling being approximately £300, whilst the furnishing, as carried out by Messrs. Heal and Sons, of Tottenham Court-road, which includes furniture, linoleum, rush mats, curtains, toilet ware, table ware for six people, fireproof kitchen ware, and bedding costs about £325. The life of a hut is estimated at from 15 to 20 years. The lighting and ventilating arrangements are good, the upper halves of the 12 windows being arranged as fanlights. The conversion of these huts may help towards the solution of the house famine, though the price, reasonable enough, is none the less too high for the small man desiring to own his home. Moreover, while the life of the hut is stated to be 15 years or more—and this need not be challenged—the premises are liable to supervision by local authorities at the expiration of a five years' licence.

#### TRAVELLING HEALTH EXHIBITIONS.

THE National Union of Women has long made the travelling child welfare exhibition into a fine art as a method of public instruction, and the National Association for Combating Tuberculosis has made similar if sporadic efforts in popularising its own activities. At a recent meeting of the Medical Council of the People's League of Health, held under the chairmanship of Sir G. Sims Woodhead, the honorary organiser, Miss Olga Nettersole, outlined her scheme for public travelling exhibitions as one channel to be employed by the League for the dissemination of knowledge regarding health. The exhibitions would cover the whole field of physical, mental, and moral health, with sections, such as tuberculosis, food, housing, waste, teeth, eyes, parentage, hygiene and respiration, child welfare, venereal disease, crime, alcohol, physical education and gymnastics. The scheme was adopted on the understanding that other associations should be invited to co-operate with the League of Health in the arrangement of the exhibitions.

## THE NORMAL VITAL CAPACITY IN MAN AND ITS RELATION TO THE SIZE OF THE BODY.

THE IMPORTANCE OF THIS MEASUREMENT AS A  
GUIDE TO PHYSICAL FITNESS UNDER DIFFERENT  
CONDITIONS AND IN DIFFERENT CLASSES  
OF INDIVIDUALS.<sup>1</sup>

By GEORGES DREYER, M.A., M.D.,  
PROFESSOR OF PATHOLOGY, UNIVERSITY OF OXFORD.

(From the Department of Pathology, University of Oxford.)

DURING the last few years questions relating to the vital capacity of man have acquired prominent importance, since this measurement has been a decisive factor in the selection or exclusion of candidates for our Flying Service. A definite minimum standard of "vital capacity" was fixed, more or less arbitrarily, for the admission of cadets to the Royal Air Force, and standards were also decided upon for the grading of flying officers for different types of service. In laying down rules in this connexion, the question of the size of the man was entirely disregarded as though of no consequence, and the standards were arrived at simply as the result of examining a number of successful pilots, and determining their average vital capacity.

### PIONEER WORK OF JOHN HUTCHINSON.

Justification for this arbitrary course was possibly found in the fact that no definite relationship between vital capacity and size was believed to exist, and that vital capacity was regarded as an extremely variable measure in different individuals, although the question of its relation to size had been approached in the remarkable and fundamental work of John Hutchinson as long ago as 1846. He claimed that vital capacity increases in a simple arithmetical progression with increasing height, and believed that he had disproved the existence of any definite relationship between vital capacity and either body weight, stem length, or chest measurement.

Although his work stands out as a pioneer achievement by one who realised, as none before or since has done, the vast importance and wide scope of the problem which he attacked, and forms a model of careful and accurate observation and measurement, yet, as will be shown in this paper, his mathematical analysis of his results failed to reveal the true relationship which vital capacity bears to certain other body measurements. The conclusions at which he arrives are as follows:—

1. That there exists a definite relationship between *standing height* and vital capacity, and he lays down the rule "that for every inch of height (from 5 ft. to 6 ft.) 8 additional cubic inches of air at 60° are given out by a forced expiration."

2. That, as regards the influence of *weight* on vital capacity, the vital capacity increases from the 7st. men to the 12st. men, and then becomes more or less irregular. Further, that it may be said that the vital capacity increases nearly in the ratio of 1 cubic inch per pound from 105 lb. to 155 lb., and that from 155 lb. to 200 lb. this increase is over-powered, and there is a loss of 39·5 cubic inches as the effect of weight.

3. That, in relation to *circumference of chest*, "contrary to what I ever expected, and agreeable to the opinion of others, I do not find there exists any direct relationship between the circumference of the chest and the vital capacity." And he concludes, having analysed his tables: "Hence the absolute breadth of chest is not a direct, ready guide to estimating the vital capacity."

In referring to these remarkable observations of Hutchinson, one cannot but express the greatest admiration for the scientific manner in which they are collected. The fact that the conclusions which I, drawing upon his material as well as my own, have reached in regard to vital capacity

and various body measurements differ from his on practically every single point, cannot affect my profound admiration for this quite unusual piece of pioneer work—an admiration to which I cannot better testify than by quoting the fine sentences with which he ends his exhaustive and excellent treatise on the Respiratory Functions:—

"The matter of this communication is founded upon a vast number of facts—immutable truths, which are infinitely beyond my comprehension. The deductions, however, which I have ventured to draw therefrom, I wish to advance with modesty, because Time, with its mutations, may so unfold Science as to crush these deductions, and demonstrate them as unsound.

Nevertheless, the facts themselves can never alter, nor deviate in their bearing upon respiration—one of the most important functions in the animal economy."

### THE AUTHOR'S RESULTS.

Before entering into detailed discussion of my results, it would be well to state here that the result of my investigations has enabled me to establish definite relationships between vital capacity and body surface, body weight, stem length and chest measurement, and to show that vital capacity is *not* a simple function of height, as Hutchinson claimed. In order of importance the relations are as follows:—

1. The vital capacity is a function of the *weight*. This can be expressed in the formula  $\frac{W^n}{V.C.} = K_1$  where W is the net weight of the body expressed in grammes, V.C. the vital capacity expressed in cubic centimetres, and the power n is approximately  $\frac{3}{2}$ , though more accurately 0·72, and  $K_1$  is a constant. As it is already established that  $\frac{W^n}{S} = K_2$  where W = net weight, S = body surface, and the

power n is approximately  $\frac{2}{3}$  though more accurately 0·72, it follows that *the vital capacity is a simple function of the body surface*. In other words, that the smaller and lighter individual, with his relatively larger surface, has a greater vital capacity per unit of body weight than the larger individual.

2. The relation between the vital capacity and *stem length* can correctly be expressed by the formula  $\frac{\lambda^n}{V.C.} = K_3$  where  $\lambda$  = stem length in centimetres, V.C. = vital capacity in cubic centimetres, the power n is approximately 2, and  $K_3$  is a constant.

3. The relation between vital capacity and *circumference of chest* can be expressed by the formula  $\frac{Ch.^n}{V.C.} = K_4$  where Ch. = circumference of chest expressed in centimetres, V.C. = vital capacity expressed in cubic centimetres, the power n is approximately 2, and  $K_4$  is a constant.

4. Finally,  $\frac{\lambda \times Ch.}{V.C.} = K_5$  where  $\lambda$  = stem length in centimetres, Ch. = circumference of chest in centimetres, V.C. = the vital capacity in cubic centimetres, and  $K_5$  is a constant.

I shall now proceed to prove the existence of the above-mentioned relationships. In order to do so I will deal first with my own observations and subsequently with those of Hutchinson and other observers.

### THE AUTHOR'S OBSERVATIONS.

The data given in the following tables was obtained from 16 men and boys who were carefully selected on account of their physical fitness, and covered as widely different a range in weight, height, &c., as possible.

The weight varied from 29·8 kg. to 88·8 kg.; the standing height from 140 cm. to 186 cm.; the stem length from 71·5 cm. to 98·5 cm.; the circumference of chest from 67·5 cm. to 96·1 cm., and the vital capacity ranged from about 2300 c.cm. in the lightest to about 5100 c.cm. in the heaviest individual. The ages ranged from 13 to about 52 years.

In this paper all measures are expressed in grammes, centimetres, and cubic centimetres unless otherwise stated. The weight is net weight, without clothing; the standing height in stockinged feet is taken in the usual manner; the circumference of chest was measured by tape measure placed directly on the skin round the chest just on the nipple line. While being measured the subject was made to stand

<sup>1</sup> An abstract of this paper was read to the delegates at the Convegno Sanitario Internazionale d' Aeronautica, Rome, Feb. 15th 1919. No. 5006.

with his arms hanging loosely down at his sides, breathing normally. This method of measurement was chosen because it was found to yield more regular results for comparison than measurements taken during extreme inspiration and expiration. The subject should be encouraged to talk whilst being measured, as the muscles are then more or less perfectly relaxed. The stem length was obtained by seating the subject on the floor or a board, with his back against a perpendicular triangular projection, to which the scale is fixed. To secure accurate measurement it is necessary for him to place his hands on the floor or board, close to his body, and, drawing up his knees, to raise himself for a moment and press his os sacrum as close as possible against the scale. It will be found that different persons bend the knees to different degrees when attempting to achieve this result. In such a position a constant measurement of stem length is provided from the top of the head to the ischial tuberosities, and one that does not vary in repeated measurements of the same individual. On account of the influence of the muscles the stem length taken when the subject is seated on a chair does not afford a constant measure of an individual, nor a measure which lends itself to accurate comparison of one individual with another—a point to which Walker has also drawn attention. The measurements taken by this latter method have been found to be about 3 per cent. greater than those obtained by the methods used in this paper.

For the measurements of vital capacity a spirometer of the dry type, made by Boullite, of Paris, was selected, as it offers a minimum resistance to expiration. The measurements were taken while the subject was sitting on a high stool with his back straight. He was always first shown carefully how to proceed, and then five measurements were taken. The subject was kept in ignorance of the readings while being examined, as it was found that any such knowledge tended to interfere with the accuracy of the results. The highest reading of the five measurements is the figure recorded in the tables. In a large number of observations the highest reading was found to be about 5 per cent. greater than the mean of the five observations. The measures are all reduced to room temperature (15° C.) and 760 mm. pressure.

In Table I. are given the details of the 16 persons as regards age, weight, standing height, stem length, circumference of chest, and vital capacity. It is seen from this

table that there is an almost steady increase of vital capacity with increasing weight, while this regularity is but poorly maintained with increase in standing height.

#### *The Relation between Vital Capacity, Body Surface, and Body Weight.*

In attempting to find the best mathematical expression for the relationship between body weight and vital capacity it was found that the body weight to the  $n$ th power, divided by the vital capacity, gives a constant, and it will be further seen that the power  $n$  is approximately  $\frac{2}{3}$ , though more accurately 0.72. But since it has already been shown that  $\frac{W^n}{S} = K$  where  $W$  = net weight in grammes,  $S$  = surface in square centimetres, and the power  $n$  is approximately  $\frac{2}{3}$ , but more accurately 0.72, it follows that the vital capacity is a simple function of the body surface.

In Table II. is calculated the "vital capacity constant" from the formula  $K = \frac{W^{0.72}}{V.C.}$  as well as the vital capacity expressed in percentage of the body weight in grammes. In comparing these two columns it is obvious that there is an almost regular decrease in the percentage of vital capacity

as the individuals increase in weight, while the "vital capacity constant" does not show any periodical change with the increase in weight, the variations only being such as depend on slight individual differences. It is further seen that the mean vital capacity constant is 0.69 and that the average figure representing the vital capacity as a percentage of the body weight is 6.626.

In the same table is also calculated the vital capacity from the formula  $V.C. = \frac{W^{0.72}}{0.69}$  (i.e., as a function of the surface), and from the average vital capacity percentage, 6.626, as well as the percentage differences between the observed figures and those calculated under the two procedures. In the first case the greatest individual deviations of the observed from the calculated figures are + 6.73 per cent. and - 3.32 per cent., while the average deviation is only 1.85 per cent. If, on the other hand, the vital capacity is calculated as a percentage of the body weight, the greatest individual deviations become as much as + 12.82 per cent. and - 17.97 per cent., the average deviation being 5.87 per cent., or about three times as large as in the former case. From this there is no doubt that the formula expressing the vital capacity as a function of the body surface represents the experimental data in a highly satisfactory manner, while the same data cannot rightly be expressed in percentage of body weight.

In Table III. the observations are arranged in eight groups, by grouping together the individuals of approximately the same weight and averaging their vital capacity. The vital capacity constant and the vital capacity expressed as percentage of the body weight are then calculated. It is again seen that the percentage of vital capacity decreases with almost absolute regularity from 7.819 per cent. in the lightest group to 5.77 per cent. in the heaviest group, while the vital capacity constant shows no periodic deviation.

In the same table are calculated the vital capacity as a function of the surface, and also as a simple function of the weight. In the former case the percentage deviation is only 1.57, while in the latter it is 5.23, taking into consideration the number of individuals in each group, or more than three

times as great. It is obvious that the greater the range of weight covered by the observations the greater must be the difference in the results arrived at by the two methods of calculation.

If, instead of making use of the best value for  $n$  (0.72) in the formula one uses, for the sake of convenience, the power  $\frac{2}{3}$ , the average  $K$  for the 16 observations is 0.380, and

the percentage difference between observation and calculation increases from 1.58 in the case of the best  $n$  (0.72) to 2.46, taking  $n$  as  $\frac{2}{3}$ . Whenever a great range of weight is covered by the observations it becomes imperative to make use of the best  $n$  (0.72) in the formula, while this is of less importance when only a relatively small range of weight is covered.

In Table IV. are calculated my own observations on vital capacity, according to Hutchinson's idea that it increases in a simple arithmetical progression with increasing height. By applying this method it was ascertained that the best approximation to be found was that for each 1 cm. increase in height there is an increase of 65 c.cm. in vital capacity. In this table the greatest individual differences between the calculated and observed figures are seen to be + 15.39 per cent. and - 13.42 per cent., while the average difference between calculation and observation is 6.02 per cent.—more than three times greater than the deviation found if the vital capacity be calculated as a function

of the body surface by means of the formula  $V.C. = \frac{W^{0.72}}{K}$ , where the percentage deviation is found to be as little as 1.85.

It is further of interest to note that if the vital capacity be calculated as a simple function of the height the percentage deviation is even larger than if the vital capacity be calculated as a simple function of the body weight—a procedure which has already been proven to be entirely fallacious.

Both from this table and from Table I. it will also appear that the vital capacity of man is not (as claimed by Hutchinson) a simple function of the height, since it does not increase at a fixed rate with each unit increase in height, but irregularly, and in the following manner. From a certain point the rate of increment of vital capacity per unit increase of height at first quickens, but presently a maximum is reached at a certain body height, and thereafter the rate of increment of vital capacity diminishes for a period before it again increases.

#### The Relation between Vital Capacity and Stem Length.

In Table V. the 16 observations are arranged according to their stem length. It is seen that, with increase in stem length there is also a more or less regular increase in vital capacity, though the regularity is very much less pronounced than was the case when the same observations were arranged by weight. The mathematical relationship

between stem length and vital capacity was found to be  $\frac{\lambda^n}{V.C.} = K$  where the power  $n$  is approximately 2. In Table V. this constant is calculated, as well as that of the vital capacity from the formula  $V.C. = \frac{\lambda^2}{1.9}$ . Looking at the column where the constants are given it will be found that, though they exhibit considerable individual variations, there is no evidence of periodicity. By applying the formula it

Average ...				6.02	Average ...				1.90	5.76

is made clear that there is an average percentage deviation of observation from calculation of 5.76. This percentage deviation is nearly three times as great as in the case where the vital capacity is calculated as a function of the surface, and only slightly smaller than if it be calculated as a simple function of the weight. Such a considerable percentage deviation of observation from calculation is caused by the fact that the stem length in individuals of the same weight varies considerably. That this interpretation is true becomes patent when we arrange the observations in five groups according to their stem lengths and average their vital capacities, as done in Table VI. In this case the percentage deviation of observation from calculation of the vital capacity, using the formula  $V.C. = \frac{\lambda^2}{1.9}$ , is only 3.54, while

the percentage deviation found if the vital capacity be calculated as a simple function of the body weight hardly diminishes by grouping but remains more or less unchanged.

If we consider for a moment the significance of this relationship which has been found to exist between stem length and vital capacity, it is easy to demonstrate that it is entirely rational and must exist in view of the relationship which has been shown to hold between weight and stem length. The same considerations will make it clear that there exists no definite relationship between standing height and vital capacity.

In an unpublished analysis which I made nearly ten years ago of a number of existing observations of standing height and body weight in man I found it was impossible to demonstrate any simple regular relationship between these two measurements. On the other hand, in different animals a definite relationship between stem length and weight was to be traced. This relationship could be expressed by the formula  $\frac{W^n}{\lambda} = K$  and the power  $n$  is approximately equal to  $\frac{2}{3}$ . It was therefore probable by analogy that a similar relationship between stem length and weight would exist in

man. This point was cleared up, at my suggestion, by Dr. Ainley Walker. The results of his investigations have already been published, and proof given that the relationships between stem length and body weight can be

expressed by the same formula in animals and man, and that the formula  $\frac{W^n}{\lambda} = K$ , where the power  $n$  is approximately  $\frac{1}{2}$ , holds good.

As we have just seen that  $\frac{W^{\frac{1}{2}}}{V.C.} = K$ , and also that  $\frac{W^{\frac{1}{2}}}{\lambda} = K$ , it follows directly that  $\frac{\lambda^2}{V.C.} = K$ , which exactly represents the formula which was deduced from the experimental data.

#### The Relationship between Circumference of Chest and Vital Capacity.

In examining the relationship between the circumference of the chest and the vital capacity during normal breathing it was found that this relationship could be expressed by the formula  $\frac{Ch^n}{V.C.} = K$ , and the power  $n$  was again found to be approximately 2.

In Table VII. the observations are arranged according to the chest measurements. It is seen that with increase in chest measurement there is also a more or less regular increase in vital capacity, though exhibiting similar irregularities as in the case of the stem length, the individual variations here also being much more marked than if they were arranged according to weight. In the same table are also given the individual constants calculated from the formula  $\frac{Ch^2}{V.C.} = K$ , as well as the vital capacity calculated from the formula  $V.C. = \frac{Ch^2}{1.82}$ . Here, again, it will be observed that there is no periodic variation in the size of the constant, the variations being caused only by individual differences. The percentage deviation of observation from calculation is found to be 5.8—a deviation practically identical with that found if the vital capacity be calculated

as a function of the stem length by the formula  $V.C. = \frac{\lambda^2}{K}$ , while it is about three times as great as when the vital capacity is calculated as a function of the body surface by the usual formula. If these observations are arranged in five groups according to the chest measurement and the vital capacity averaged (as done in Table VIII.) the percentage deviation of calculation from observation is reduced to 4.27, or a difference somewhat larger than the deviation found if the vital capacity is calculated by the stem length by means of the proper formula.

The above-mentioned relationship between vital capacity and chest measurement having been established, it became a mathematical necessity that a relationship similar to that which has already been shown between stem length and weight should exist between weight and circumference of chest; in other words, that  $\frac{W^n}{Ch} = K$ , and the power  $n$  is approximately  $\frac{1}{2}$ . The proof of the existence of such relationship will be given below.

#### Relationship Between Circumference of Chest and Body Weight.

In Table IX. are given the weights of the 16 persons and the corresponding chest measurements. There is also to be found the constant  $K = \frac{W^{\frac{1}{2}}}{Ch}$ , as well as the chest

measurement calculated from the formula  $Ch = \frac{W^{\frac{1}{2}}}{0.457}$ . 0.457 is the average constant for the 16 individual observations. The percentage deviations of the observed from the calculated circumference of chest are also given.

It is clear that the chest constant shows no periodic variations, but only such irregularities as depend on individual differences. The average percentage deviation of observation from calculation is only 2.62—a difference somewhat smaller than that found by Walker in calculating the stem length from the weight. The mean deviation of observation from calculation, as determined by the method of least squares, is found to be 3.25, which indicates that if an individual be found to differ by about 6 per cent. from the normal chest measure for his weight he is probably abnormal in this respect; and if he exhibit a chest measurement 12 per cent. smaller or larger than the theoretical he is almost certainly abnormal. Hence it follows that the formula

$\frac{W^n}{Ch} = K$ , where the power  $n$  is approximately  $\frac{1}{2}$ , expresses the relationship between body weight and circumference of chest in an extremely satisfactory manner.

If from the data given in Table I. we calculate the average constant for stem length and weight by means of the formula  $\frac{W^{\frac{1}{2}}}{\lambda} = K$ , it is found to be 0.449. If we use this constant in calculating the stem length from the weight by the formula  $\lambda = \frac{W^{\frac{1}{2}}}{0.449}$ , the average percentage deviation of observation from calculation is 2.58, while the mean percentage deviation by the method of least squares is 3.21—or practically identical with those deviations above mentioned, where the chest measurement was calculated from the weight.

From the constants found in the two cases—viz., 0.457 (in case of the chest measurement) and 0.449 (in case of the

stem length)—it follows that in the normal healthy man the circumference of chest is, on an average, about 1.5 per cent. smaller than the stem length, though in a fair number of the individual cases the chest measurement may be greater than the stem length.

*The Relationship between Stem Length, Circumference of Chest, and Vital Capacity.*

From what has been said above with regard to the relationships of the vital capacity to stem length and chest measurement, and their relationships to body weight, it follows that  $\frac{\lambda \times \text{Ch.}}{\text{V.C.}} = K$ . In Table X. this constant is calculated from

Average...					1.85	...	4.44	Average ...			0.210	...	2.74

the individual data given in Table I. The average constant is 1.85, and by means of this constant the vital capacity is calculated from the formula  $\text{V.C.} = \frac{\lambda \times \text{Ch.}}{1.85}$ , as well as the percentage deviation of observed from calculated figures. The average percentage deviation is found to be only 4.44, as compared with 5.76 and 5.80 if the vital capacity were calculated from the stem length and the circumference of chest respectively.

That the agreement between observation and calculation is improved by taking into account both stem length and chest measurement was a priori to be expected, as we are making use of two dimensions instead of one. Moreover, the two measures often tend to correct each other. If, for instance, a person is found to have too big a stem length in proportion to his weight, the circumference of chest is usually too small in proportion to weight. We see, therefore, that the errors thus introduced will be partly, and sometimes entirely, eliminated by taking both measurements into account.

From the various formulæ already given, it follows directly that  $\frac{W^n}{\lambda \times \text{Ch.}} = K$  where the power  $n$  is approximately  $\frac{2}{3}$ . That this is the case will be seen from Table XI. where the constant  $K = \frac{W^{\frac{2}{3}}}{\lambda \times \text{Ch.}}$  is calculated from the data in Table I.  $\lambda \times \text{Ch.}$  is also here calculated

from the formula  $\lambda \times \text{Ch.} = \frac{W^{\frac{2}{3}}}{0.21}$ , as well as the percentage difference between  $\lambda \times \text{Ch.}$  observed and  $\lambda \times \text{Ch.}$  calculated. The percentage deviation of observation from calculation is found to be 2.74—or only slightly greater than when the stem length or the chest measurement individually are calculated from the body weight.

Though the relationships here shown to exist in normal man between vital capacity, body weight, stem length, and chest measurement are all rational relationships, there can be no question that the most accurate manner in which to express the vital capacity is as a function of the body surface, by means of the formula  $\frac{W^n}{\text{V.C.}} = K$ , where  $n$  is approximately  $\frac{2}{3}$ , or, more accurately, 0.72.

The importance and utility of the other relationships at once become obvious when one begins to deal with individuals whose weight has become abnormal as a result of disease—as, for example, in the study of the effect of pulmonary tuberculosis and other diseases definitely resulting in emaciation on vital capacity. For it is evident that with loss of weight a vital capacity which was definitely abnormal when calculated in relation to the normal weight of the person might appear normal if calculated in relation to the reduced weight found during disease, whereas no such interference with the size of the constant would take place if the vital capacity were calculated in relation to stem length, and only to a small extent if calculated in relation to circumference of chest.

By taking all three relationships into account information is therefore gained not only as regards the vital capacity, but also as regards the condition of weight, whether it be increased or decreased beyond the normal measure.

*HUTCHINSON'S OBSERVATIONS COMPARED WITH THE FOREGOING RESULTS.*

Before dealing any further with my own observations, which have led to conclusions so contrary to those of Hutchinson, it is important to consider his observations, as well as those of others, in the light of what has been said above. I have already given in a previous paragraph the conclusions at which Hutchinson arrived. I shall now proceed to show not only that his observations entirely bear out my own results, but also to point out why he arrived at some of his own erroneous conclusions.

Table XII. is a reprint of Table E (p. 163) in Hutchinson's paper, where the results of his observations on the vital capacity of 1285 men are arranged, the grouping being according to weight, but at the same time keeping the height in view. It is at once seen that the vital capacity seems to increase to a maximum at the weight of 150 lb., and then to become stationary, or even decrease. He concludes himself: "It seems the vital capacity increases 42 cubic inches with the weight from 100 to 155 lb., and from 155 to 200 lb., the effect is balanced by minus 5 and plus 5 cubic inches."

It was of interest and importance to examine this marked discrepancy between the results obtained in my own observations, and the mean of results obtained by Hutchinson in observing such a large number of people, and to find out whether the discrepancy was real or only apparent. By analysis of the data given in Table D (p. 162) in Hutchinson's paper, from which he himself had constructed the table reprinted above, it soon became evident that the reason why he reached results so absolutely contrary to those which I have obtained was the manner in which he arrived at his average vital capacity for each given weight. The fact is that he entirely disregarded the number of individuals in each of the series from which he was making up his groups; in other words, in arriving at the average vital capacity for the group, if he has a single case with a very small vital capacity, he gives the same value to this as to 50 or more cases which have a large vital capacity, or vice versa. Such a procedure naturally leads not only to marked irregularities, but to definite errors in the estimation of the proper relationship between vital capacity and body weight.

To prove this point, Table XIII. has been constructed from Hutchinson's Table D (p. 163), and here due consideration has been given to the number of cases in each series in arriving at the average vital capacity for each group. In the same table are also given the values for the constant  $K = \frac{W^{\frac{2}{3}}}{\text{V.C.}}$  as well as the vital capacity expressed in percentage of body weight.

It is seen that the vital capacity increases gradually and steadily from the lowest to the highest weight. There is, in fact, no evidence whatever that from a weight of 150 lb. upwards the vital capacity becomes stationary or decreases, as appears to be the case from Hutchinson's

Table XII. above. It is therefore obvious that his observations are so far entirely in agreement with my own. From Table XIII. it is also seen that if the vital capacity be expressed in percentage of body weight, there is a steady and regular decrease in the percentage as the weight increases, falling from 1.63 per cent. in the lightest, to

190	223	1235	Average ...	0.123	...	0.72	1.47	...	...	3.86

1.29 per cent. in the heaviest, group; while if it be expressed in relation to the body weight to the  $\frac{2}{3}$  power, the relationship is constant. Thus in Hutchinson's observations also we find that the vital capacity is a function of the surface of the body,

correctly expressed by the formula  $\frac{W^n}{V.C.} = K$ , where the power  $n$  is approximately  $\frac{2}{3}$ , so proving from his own data and observations how erroneous was his conclusion that no definite relationship between vital capacity and body weight could exist.

Furthermore, in Table XIII. the vital capacity is calculated as a function of the body surface by means of the formula

$V.C. = \frac{W^{\frac{3}{2}}}{0.128}$  and also as a simple function of the body

weight from the formula  $V.C. = W \times 1.47$ , as well as the percentage difference between observation and calculation by these two procedures. In the first case the average percentage deviation is only 0.72, taking the numbers in the groups into consideration, while in the latter case the average deviation is as much as 3.86 or about five times as great as in the former.

To take the matter a step further, we will now test the validity of Hutchinson's statement that there exists a simple relationship between the height of the individual and his vital capacity. In Table XIV. are given the average vital

capacities for Hutchinson's observations, detailed in Table A (p. 156), as tabulated by him for heights ranging from 5 ft. to 6 ft. inclusive; also the average vital capacities for the corresponding heights arrived at by my calculation, which takes into account the number of individuals in each series forming the groups, as should obviously be done. There is

also given the series of vital capacities in arithmetical progression as calculated by Hutchinson; and, finally, the percentage deviation of observation from calculation. It is seen that, considering the number of individuals in each group, this deviation is as much as 2.37 per cent., which is an error more than three times as great as the percentage difference found above between observation and calculation; for when the same data was expressed as a function of the body surface the deviation was only 0.72 per cent. Thus it is evident from Hutchinson's observations, as well as from my own, that the vital capacity of man is not a simple function of the body height, as he contended, since it increases in an irregular manner and not at a fixed rate with each unit increase in height.

#### The Variations of Vital Capacity in Normal Individuals.

Having once established the actual existing relationships between vital capacity and different body measurements, it is necessary to determine the magnitude of the deviations from the average met with in normal and healthy individuals, as it is otherwise impossible to decide whether the vital capacity found in any given person should be considered as normal or abnormal.

In the case of the 16 persons examined, the average constant in the formula  $\frac{W^n}{V.C.} = K$ , was found to be 0.380 if

the power  $n$  be taken as  $\frac{2}{3}$  and 0.690 if the best power, 0.72, be used. The mean deviation of observation from calculation, employing the method of least squares, was found in the two cases to be 3.56 and 2.64 per cent. respectively, or distinctly greater if the power  $\frac{2}{3}$  is used. This indicates that if a person is found to have a vital capacity 6 per cent. smaller or larger than that calculated from his surface by means of

the formula  $\frac{W^n}{V.C.} = K$ , where  $n$  is 0.72, it is probable that he has an abnormal vital capacity, and if the vital capacity is 10 per cent. above or below the normal it is almost certain that he is abnormal in this respect.

If we deal with the material of Haldane and FitzGerald on 11 men in a similar manner we find that if the vital capacity be calculated as a function of the surface the mean deviation by the method of least squares for the individual observations are as much as 15.8 per cent., or a mean deviation five times greater than that found in my own observations. The explanation of this enormous difference is most likely to be found in the fact that their observations have been carried out on a highly mixed material, and therefore necessarily exhibit great individual variations. The existence of such individual differences and their causes is a factor of the utmost importance in attempting to fix definite standard limits of vital capacity in normal persons, as will be shown in the following paragraph.

#### Variations of Vital Capacity in Normal Individuals of Different Classes and Occupations.

In the course of further observations on the vital capacity in apparently normal persons of various classes and positions it became evident that a distinct variation was found in the vital capacity constant, resulting upon the varying nature of the life and habits of the individuals in question. It was therefore obvious that unless due attention were paid to these influences any fixed standard would become vitiated by them. Fortunately, we possess in Hutchinson's careful observations a material which, when properly used, gives us important information with regard to the value of the vital capacity in judging the physical fitness and development of different classes of the population.

To demonstrate this fact I have compiled and calculated some 1900 cases from Hutchinson's recorded observations. I have classified these men according to their occupation, and calculated the vital capacity constant from the formula

$\frac{W^{\frac{2}{3}}}{V.C.} = K$ . The results of the calculation are given in

Table XV. Before calculation Hutchinson's observations, recorded in pounds and cubic inches, were reduced to grammes and cubic centimetres, the weight of the body being the net weight without clothing. From the construction of the formula it is obvious that the larger the constant the smaller the vital capacity for any given weight. The classes are arranged according to vital capacity, that with the highest vital capacity heading the list, and the remainder being graded in order of decreasing rate.

TABLE XV.

- A) Number of individuals in group.  $W^{\frac{2}{3}}$   
 (B) Vital capacity constant:  $K = \frac{W^{\frac{2}{3}}}{V.C.}$   
 (C) Physical fitness (per cent.).

(A)	Occupation.	(B)	(C)	(A)	Occupation.	(B)	(C)
172	Chatham recruits.	0.412	100.0	69	Grenadier Guards.	0.441	95.4
27	Pugilists.	0.420	98.1	20	Draymen.	0.443	93.0
563	Woolwich marines.	0.425	96.9	23	Pressmen.	0.450	91.5
119	Seamen.	0.426	96.7	158	Mixed classes.	0.455	93.4
74	Thames police.	0.427	96.4	82	Miscellaneous.	0.458	89.9
30	Horse Guards.	0.433	95.1	47	Compositors.	0.467	88.1
130	Metropolitan police.	0.434	94.8	101	Gentlemen.	0.488	84.3
92	Fire brigade.	0.439	93.7	116	Paupers.	0.493	82.5

It is seen that Hutchinson's "Chatham Recruits" represent the best class, and it is interesting to note that he himself characterises these individuals as "a remarkably fine body of young men." Taking the constant calculated from this group of men as representing 100 per cent. of physical fitness, the fitness of the other classes appears in the table in percentage of this class. It is noted that the percentage falls steadily from 100 per cent. in the best class in a way that might be expected from the nature of the occupations of the different groups, until we come to paupers, with about 20 per cent. less vital capacity than the best group. It will be observed, probably with some astonishment, how very low is the position taken in this respect by the class of gentlemen in 1846—a fact doubtless connected with the life and habits of gentlemen in London at that date.

Table XV. indicates that it would appear promising to make use of the vital capacity in its proper relation to the size of the body to obtain important knowledge regarding the physical condition of the various classes of the population, and to express this in relation to the standard of perfect health.

In Table XVI. I have arranged my own observations of a few classes of the people of the present day. Here also the constant is calculated from the formula  $\frac{W^{\frac{2}{3}}}{V.C.} = K$ , the weight is net weight in grammes, without clothing, and the vital capacity expressed in cubic centimetres. The constants

TABLE XVI.

- A) Numbers of individuals in group.  $W^{\frac{2}{3}}$   
 (B) Vital capacity constant:  $K = \frac{W^{\frac{2}{3}}}{V.C.}$   
 (C) Physical fitness (per cent.).

(A)	Occupation.	(B)	(C)
16	Men and adolescents selected for physical fitness ... ..	0.380	108.3
14	Oxford undergraduates (own).	0.380	108.3
959	" " (Schuster's).	0.381	108.1
7	Boy Scouts.	0.390	105.7
12	Men (mixed upper class).	0.416	99.0
12	" " (lower " " ).	0.445	92.6
12	Females (mixed classes).	0.493	83.6

are therefore directly comparable with those in the above table, and the percentages were expressed in percentages of Hutchinson's "Chatham Recruits," equalling 100 per cent. of fitness.

It is most interesting to observe from this table how the active, athletic class of gentlemen of the present day heads the group of my own observations with actually 9 per cent. more relative fitness than the above-mentioned "remarkably fine body of young men."

From observations that I have made it seems clear that the difference in vital capacity exhibited by different classes has nothing to do with fundamental bodily deficiencies, but is simply a result of conditions depending upon occupation and mode of life. Taking, for example, two sets of boys from the same elementary school, from similar homes and living under similar conditions—with the exception, however, that one of the two sets of boys were Boy Scouts—it was

found that the latter had, on an average, a vital capacity constant approaching the magnitude of that found in Oxford undergraduates, and exhibited a vital capacity of about 15 per cent. greater than that of the lads who were not Boy Scouts. The army training has brought out, in those who have undergone it, the same marked increase in vital capacity when they are compared with similar classes of the population who have not had this physical training.

#### The Fixing of Standards of Normal Vital Capacity.

From a comparison of the results obtained on the limited number of individuals hitherto examined sufficient information has been gathered to make it clear that it would not be justifiable to employ the data collected by Hutchinson for the fixing of standards for the different classes of the population at the present date. Before definite and valid standards can be arrived at it is inevitable that a relatively large number of subjects drawn from the different classes and trades of the population must be examined in regard to vital capacity and various body measurements. To help to carry out this extensive scheme the Medical Research Committee have already undertaken to give financial aid, and it is hoped that this inquiry may take its place in a larger scheme for the study of anthropometric standards.

At the present moment I can only consider the standard fixed from the examination of Oxford undergraduates as an accurate standard for this particular class of population. The average constants arrived at from my own observations upon

14 Oxford undergraduates were as follows:  $\frac{W^{0.72}}{V.C.} = 0.69$ ;  $\frac{\lambda^2}{V.C.} = 1.9$ ;  $\frac{Ch.^2}{V.C.} = 1.82$ .

Before accepting these constants, obtained from a very limited number of observations, as valid standards it became important to see how they would compare with the constants that could be obtained from calculation of Schuster's extensive series of measurements of vital capacity in 959 Oxford undergraduates. In Table XVII. I have

made an abstract from Schuster's data. The weights are net weights in grammes, arrived at by the subtraction of the weight of clothing, using the proper reduction factor; the stem lengths in centimetres are the stem lengths recorded by Schuster, reduced by 3 per cent. This reduction is necessary to make the measurements comparable with my own observations, for it was found, as previously stated, that the measurement obtained by seating a person on a chair is about 3 per cent. greater than that obtained by measuring the stem length in the manner used in my own observations. The vital capacities are given in cubic centimetres.

In this table is calculated the constant K, by means of the formula  $\frac{W^n}{V.C.} = K$ , both when the power n is taken as  $\frac{2}{3}$  and when the best n (0.72) is used, as well as the K for the formula  $\frac{\lambda^2}{V.C.} = K$ . The constants found are  $\frac{W^{\frac{2}{3}}}{V.C.} = 0.381$ ;  $\frac{W^{0.72}}{V.C.} = 0.690$ ;  $\frac{\lambda^2}{V.C.} = 1.90$ . It is striking to see that the constants arrived at by an analysis of this

extensive series of careful observations of 959 Oxford undergraduates are absolutely identical with those found in my own very limited number, and also the same as those obtained in the 16 observations on persons selected for their physical fitness. In view of this fact, therefore, it seems entirely justifiable to accept these standards as true standards for the measurement of a condition of the most perfect health and fitness at the present time.

#### *Vital Capacity in Relation to Diagnosis of Disease.*

Since the vital capacity has been shown to exhibit such marked variations in the different classes of the population, depending upon their mode of life, and has also been shown during the war to be influenced by the strain on flying men (continued flying in high altitudes resulting in a temporary diminution of vital capacity), it is likely that various forms of fatigue would be found to influence it in the same manner. If this be the case it is probable that certain diseased conditions, more particularly of the respiratory and circulatory organs, would lead to a distinct diminution in the vital capacity. One's mind naturally turns at once to the question of the effect of pulmonary tuberculosis on vital capacity. This application is not novel, as already in 1846 Hutchinson had made use of the study of vital capacity as a help in diagnosis of diseases of the lungs—more particularly tuberculosis. He showed that cases of pulmonary tuberculosis exhibited a vital capacity distinctly inferior to what he considered normal, judging from the height of the individual.

From what has already been said it is self-evident that it is impossible to deduce valuable conclusions regarding the effect of disease on vital capacity before definite standards have been worked out for the various classes of the normal population. By means, however, of a few undoubtedly fairly accurate standards so far arrived at it has been possible to approach the study of the effect of pulmonary tuberculosis on vital capacity. And although it would be premature at the present moment to express a final opinion as regards the value of this method, it can already be stated that it has yielded very promising results in the examination of about 150 cases of pulmonary tuberculosis which I myself have dealt with in collaboration with Dr. L. S. T. Burrell, of the Brompton Hospital. The particulars of the results obtained will be published in detail when sufficient material has been collected and analysed. At the present moment I can only state the following: that I have been able, without seeing the cases or knowing anything about the diagnosis, but simply from measurements (recorded and sent to me by Dr. Burrell) of the vital capacity and the various body measurements mentioned above and by subsequent calculation, to classify these persons as normal individuals, or as examples of mild, of moderate, or of severe pulmonary tuberculosis, in practically absolute agreement, as afterwards appeared, with the clinical diagnosis and classification made at the time at the Brompton Hospital.

From the experience already gained it seems likely that the careful study of the vital capacity in its proper relationship to body size will give important information as to the beneficial effects derived from sanatorium treatment of pulmonary tuberculosis, and also enable us to distinguish between those cases likely to benefit from continued treatment and those for whom it would be of no further profit.

#### CONCLUSION.

From a consideration of the results arrived at in the present communication it seems likely that systematic measurement of the "vital capacity" and various body measures indicated above, in adults and adolescents in different trades and occupations, and in different ranks of life, will afford most important information from the point of view of national health, and will throw light upon the value of such measures as may be contemplated for the improvement of the general health and well-being of the people of this and other countries.

## THE ÆTIOLOGY OF INFLUENZA.

By G. E. BEAUMONT, M.A., B.M. OXON., M.R.C.P.,  
D.P.H. LOND.,

TEMPORARY ASSISTANT PHYSICIAN, METROPOLITAN HOSPITAL, E.;  
RADCLIFFE TRAVELLING FELLOW, UNIVERSITY OF OXFORD;  
TEMPORARY CAPTAIN, R.A.M.C.

THE following is a section of a longer article dealing with influenza from the point of view of clinical signs and symptoms, and describing the results obtained by various therapeutic methods.

#### *Ætiology of the Disease.*

The cause of the disease will be discovered in the laboratory. Clinical observations enable one to diagnose it in the great majority of instances, but until the infective agent is described and uncontroversially recognised as such, diagnosis of obscure cases will remain doubtful.

In respect of influenza, bacteriologists are divisible into two classes—those who believe in the Pfeiffer concept, and the rest. At the commencement of this epidemic the generally accepted view was that Pfeiffer's bacillus is the cause of influenza, and it is interesting to see what has arisen to shake one's confidence in this orthodoxy.

Pfeiffer,<sup>1</sup> in January, 1892, described a bacillus as occurring in the sputum of acute cases of influenza. These organisms, he stated, were constantly present, but do not occur in the bronchial secretion of other bronchial or pulmonary affections. The bacillus has the following characteristics: It is very minute, about half the length, and the same thickness as the bacilli of Koch's mouse septicæmia. It is non-motile. It stains with difficulty with the aniline dyes, but when stained shows a granule at each end retaining the stain and a central unstained portion, showing only the outline of the sheath. The bacillus thus looks like a diplococcus, and where two such bacilli are placed end to end they look like a chain of four spherical cocci.

Kitasato in the same paper describes the cultural characteristics of the bacillus. It does not grow below 28° C. It grows well in broth and on glycerine agar at 37° C. The growth in broth appears as whitish small granules or flocculi, and the broth does not become turbid. The cultures soon die out—stained specimens from the cultures show the same bi-polar staining.

Pfeiffer later showed that the addition of blood to the culture medium greatly enhances the growth of the bacillus—especially on subcultures, and for this purpose smeared blood over the surface of the agar medium.

Klein<sup>2</sup> examined films of sputum in 20 cases of influenza, during February and March, 1892, and found the bacillus of Pfeiffer present in every case. The films were stained with carbol methyl blue. The organism was a minute bacillus (0.4  $\mu$   $\times$  0.8  $\mu$ ), with rounded ends and bi-polar staining. From washed sputum pure cultures were obtained in broth, and if subcultures were made every two or three days, the growth could apparently be carried on indefinitely. Growth was also obtained on ordinary agar, and subcultures for as many as 20 generations obtained.

Films made from the cultures showed the bacilli growing in long twisted threads or chains, the bacilli being placed end to end and enclosed in a continuous sheath. In all specimens, no matter how recent, spherical or oval bacilli appear, many times thicker than the typical bacillus. The number of these spheres is greater in later than in recent cultures and the largest of them often show a vacuole in their centre or at one side.

Canon, at the same time as Pfeiffer and Kitasato and in the same paper (vide Pfeiffer<sup>1</sup>), stated that he examined influenzal blood by making cover-slip films. The films were dried, fixed in absolute alcohol, and stained in methyl blue eosin for several hours at 37° C. He states that in every case he saw 5 to 20 bacilli in each cover-slip film, and these bacilli were definite and pathognomonic of the disease. Further, he states that by using 8 to 12 drops of blood he succeeded in every case in growing the bacillus on sugar agar.

Klein<sup>2</sup> examined 43 cases, and only found bacilli in cover-glass blood films in six of these. The bacilli had the characteristics of Pfeiffer's bacillus, but in no case was a growth obtained on subculture. He concludes that "any bacilli of influenza that may gain access to the circulation lose here their vitality and are present in the blood only as dead bacilli."

Klein also performed animal inoculation experiments, using sputum containing Pfeiffer's bacilli, and broth cultures of the bacilli as the inoculum. Rabbits and monkeys were injected, but although the subcutaneous, intravenous, and intratracheal routes were employed, in no case was the disease reproduced. The position at the commencement of the present epidemic was therefore this—a bacillus

was described which was found in the sputum in every acute case of influenza; it was also seen in the blood in a certain number of cases. Attempts to reproduce the disease in animals by injecting the bacillus had failed. It was generally considered that the bacillus was only seen in material obtained from patients suffering from influenza.

Now one may say that there is considerable doubt as to whether Pfeiffer's bacillus is the cause of influenza. Many papers have been published by workers in Europe on the bacteriology of influenza during the present epidemic, and their results are by no means concordant. The examinations comprise those of posterior nasal swabs, sputum, pleural effusions, blood, and post-mortem materials—chiefly lungs and lymphatic glands. The results of these investigations are shown below.

#### Posterior Nasal Swabs.

In the following table (I.) accounts of the experiments of eight different observers have been noted, and from the results shown it will be seen that Pfeiffer's bacillus or a diplococcus has been obtained.

TABLE I.

Observer.	No. of cases.	Pfeiffer's bacillus found.	Cocci.
		Per cent.	Per cent.
Abrahams, Hallows, and French <sup>3</sup> ...	10	50	100
Whittingham and Sims <sup>4</sup> ...	50	38	100
Braxton Hicks and Gray <sup>5</sup> ...	?	80	100
Little, Garofalo, and Williams <sup>6</sup> ...	20	0	100
Averil, Young, and Griffiths <sup>7</sup> ...	16	0	100
Matthews <sup>8</sup> ...	12	100	100
McIntosh <sup>9</sup> ...	12	66·8	100
Fildes, Baker, and Thompson <sup>10</sup> ...	15	80	100

The net result of these various investigations is that Pfeiffer's bacillus has been found in 51·8 per cent. of cases of naso-pharyngeal swabs taken from influenzal patients, cocci being also found in every case.

#### Sputum.

The result of the observations shown in Table II. is that Pfeiffer's bacillus has been found in the sputum in 42 per cent. of cases.

TABLE II.

Observer.	No. of cases.	Pfeiffer's bacillus found.	Observer.	No. of cases.	Pfeiffer's bacillus found.
		Per cent.			Per cent.
Gotch and Whittingham <sup>11</sup> ...	50	8	McIntosh <sup>9</sup> ...	25	84
Braxton Hicks and Gray <sup>5</sup> ...	?	75	Fildes <sup>10</sup> ...	106	43
Little, Garofalo, and Williams <sup>6</sup> ...	20	0	Leichentritt <sup>13</sup> ...	72	60
Averil, Young, and Griffiths <sup>7</sup> ...	41	78	Löwenfeld <sup>14</sup> ...	55	71
Selter <sup>12</sup> ...	33	0	Graetz <sup>15</sup> ...	182	1·5

As regards other organisms, Gotch and Whittingham<sup>11</sup> found a Gram-negative micrococcus resembling *Micrococcus catarrhalis* in 100 per cent. of cases during the first wave of the epidemic. Little, Garofalo, and Williams found a Gram-positive diplococcus with flattened adjacent sides in 100 per cent. of cases, whereas Bernhardt<sup>16</sup> describes a Gram-positive diplococcus (*Diploccoccus epidemicus*) as occurring in all cases.

#### Pleural Effusions.

Netter<sup>17</sup> examined 12 cases (all purulent) and found Pfeiffer's bacillus in 8 per cent. Braxton Hicks and Gray<sup>5</sup> found Pfeiffer's bacillus on two occasions in pleural exudate, in addition to a diplostreptococcus. This latter organism was allied to, if not identical with, the *Streptococcus mucosus* (of Stephan<sup>18</sup>), and was found in every case of pleural effusion, but the number of cases examined is not given.

**Blood cultures.**—These have either proved sterile, yielded Pfeiffer's bacillus or a coccus (of different varieties) in the proportions shown in Table III.

The resultant of this series is that 82·8 per cent. of blood cultures have proved sterile, 7·8 have yielded Pfeiffer's bacillus, and 9·4 per cent. cocci of different varieties. The

cocci which Whittingham and Sims<sup>4</sup> found in their blood cultures were of different varieties—a streptococcus, a pneumococcus, and a *Diploccoccus mucosus* (Stephan<sup>18</sup>) in the relative proportions of 5, 1, and 1. This *Diploccoccus mucosus*

TABLE III.

\* ? How much.

was described by Stephan<sup>18</sup> at the end of the year 1916. He isolated it in an extensive outbreak of influenza in Strumpell's clinic at Leipsic, and obtained it both from blood and sputum. The cultural characteristics of this organism are described later. Post mortem Segale<sup>20</sup> obtained another coccus from heart blood. He called it the *Streptococcus pandemicus*, and finding it also in spinal fluid and lymphatic ganglia had 55 per cent. positive results in a series of 54 cases.

#### Post-mortem Material: Lungs and Lymph Glands.

In the post-mortem examination shown in Table IV. Pfeiffer's bacillus was found in 38·3 per cent. of cases, and cocci of different varieties in 47·5 per cent. of cases.

TABLE IV.

Observer.	No. of cases.	Pfeiffer's bacillus found.	Cocci.	Other organisms
		Per cent.	Per cent.	Per cent.
Abrahams, Hallows, and French <sup>3</sup> ...	28	25	96	—
Braxton Hicks and Gray <sup>5</sup> ...	?	0	?	—

Leichentritt <sup>13</sup> ...	6	100	—	—
Löwenfeld <sup>14</sup> ...	45	80	—	—

\* An organism resembling *B. pestis*.

Thus Abrahams, Hallows, and French<sup>3</sup> found a *Streptococcus longus* in 36 per cent. of cases, a diplostreptococcus in 36 per cent. of cases, and a pneumococcus in 26 per cent. of cases. Fletcher<sup>21</sup> found a meningococcus in 30·5 per cent. of cases, a pneumococcus in 8·3 per cent. of cases, and a streptococcus in 5·5 per cent. of cases. The organism found by Segale<sup>20</sup> was his *Streptococcus pandemicus*.

From the publications during the present epidemic, which have been quoted above, we see that Pfeiffer's bacillus has been isolated from—

Naso-pharyngeal swabs in 51·8 per cent. of cases.  
Sputum " 42 " "  
Pleural fluids " 8 " "  
Blood " 7·8 " "  
Lungs and lymph glands " 38·3 " "

During the epidemic various media have been devised which have been considered to have a specially selective action favouring the growth of Pfeiffer's bacillus. These are blood media in which the blood has been subjected to the action of trypsin, as in Matthews's medium,<sup>8</sup> or boiled as in Levinthal's medium.<sup>23</sup> Thus, Fildes<sup>10</sup> states "the classical blood-agar medium has been practically useless under the conditions met with," but using Levinthal's medium he recovered Pfeiffer's bacillus in a high percentage of cases. Fleming<sup>24</sup> stated that if blood is boiled with

water, and only the clear filtrate added to agar, an efficient medium for growing influenza bacilli is obtained, and I suggest that it is possible that the essential element is iron which is liberated from the hæmoglobin by boiling and present in the filtrate.

On the other side we have the records of observers who have examined large numbers of cases and used the very latest and most fashionable media, and yet failed to obtain Pfeiffer's bacillus in more than an inconsiderable percentage of cases, and we must remember that the bacillus was first isolated without the use even of the simplest form of blood medium, and was stated to grow in broth cultures.

The case for Pfeiffer's bacillus is still further weakened by the fact that it has been found in cases which are not influenzal in nature. Thus, Fildes<sup>10</sup> examined 71 naso-pharyngeal swabs from healthy individuals and found Pfeiffer's bacillus in 21 per cent. Fleischmann<sup>25</sup> has shown that Pfeiffer's bacillus may be found in healthy tonsils, and in the tonsils in diphtheria and scarlet fever; also in broncho-pneumonia occurring as a complication of measles, and in tuberculous cavities in lungs, and in bronchiectasis.

The organism does not, therefore, fulfil even the first postulate of Koch for specificity—which states that it shall be found in every case in lesions typical of the disease, and there alone. It has not been shown to be pathogenic to animals, and it only produces slight serological reactions in man during infection.

Ford Robertson,<sup>26</sup> a staunch supporter of the Pfeiffer school, states that by injection into man of a killed culture of Pfeiffer's bacilli he can at will produce a "controlled attack of influenza." How he can prove that the reaction following the giving of the vaccine differs in any way from that following the injection of any other vaccine he does not state; but to assert that an attack of the specific disease influenza is produced requires some evidence to support it, and that is not given.

If Pfeiffer's bacillus is not considered to be the cause of influenza, what alternatives are left?

First of all, the infective agent may be of small size and belong to the class of filter-passers. Nicolle and Lebaillly<sup>27</sup> showed in October, 1918, that filtered sputum of influenzal cases reproduced the disease in man when inoculated by the subcutaneous route; further, he used unfiltered sputum and injected it by the subconjunctival and nasal routes in monkeys, and produced a disease resembling influenza. Since then Gibson, Bowman and Connor,<sup>28</sup> and Rose Bradford, Bashford and Wilson,<sup>29</sup> working independently, have published results showing that a filtrable virus exists in material obtained from influenza patients (sputum, blood, pleural fluid). This virus, when injected into animals—monkeys and guinea-pigs—produces in some cases death, in others illness. Post mortem the lesions found in the lungs, trachea, pleura, and heart muscle resemble those seen post mortem in man in influenza. From this material the virus is recoverable, and by animal passage increases in virulence. It is anaerobic and can be grown by the Noguchi method.

It is thus demonstrated that a virus which is a filter-passer can be obtained from influenzal material; but whether the disease produced in the animals is influenza still requires proof. Leschke,<sup>30</sup> working with the filtrate obtained from an influenzal lung, sprayed man and produced typical attacks of influenza. In one instance two people who nursed the sprayed individual developed the disease.

Although the amount of work which has been done on filter-passing organisms in influenza is small, yet the evidence is weighty as regards the presence of a filtrable virus, but yet insufficient to prove that it is the actual causative agent either in toto or merely as a stage in the life-history of a larger organism.

*The cocci.*—Authors who have been unsuccessful in their search for Pfeiffer's bacillus, and who have not experimented with the filter-candle, have described cocci and put forward the suggestion that here we have the actual cause of the disease. Gotch and Whittingham<sup>11</sup> described a Gram-negative micrococcus occurring in all cases in the sputum and naso-pharyngeal swab cultures as the predominating organism. They inoculated it on the naso-pharynx of two healthy individuals and "produced the disease in a typical form." They therefore conclude that this micrococcus is probably the specific organism, either alone or in conjunction with *B. influenza* (Pfeiffer). The cultural characteristics of this organism are not described.

Whittingham and Sims<sup>4</sup> obtained from blood cultures streptococci, pneumococci, and an organism resembling the *Diplococcus mucosus* of Stephan.<sup>18</sup> When first isolated it is Gram-negative, but on subculture not only does its staining by Gram become variable, but it assumes a pleomorphic form—oval diplococci and bacillary forms appearing. These bacillary forms are always Gram-negative, stain readily with dilute carbol fuchsin and grow on ordinary agar. They occur mixed with the cocci in individual plate colonies.

Donaldson<sup>31</sup> has published some most suggestive notes on his bacteriological findings. In the first place he failed to find Pfeiffer's bacillus in every case examined, but he found constantly an organism previously undescribed. This is a coccus which he calls the organism "D." It is characterised by its remarkable pleomorphism.

"It may grow in the form of enormous bacilli, or as extremely long chains of giant cocci, or cocci alternating with giant bacilli of all shapes. Later on it loses this pleomorphism and comes to resemble a staphylococcus, and finally assumes the form of large deeply Gram-positive tetrads. The cultural characters vary with the different morphological phases, and it shows an extraordinary variability towards Gram's stain."

Donaldson also suggests that there may be a filter-passing stage to this organism. Rosenow<sup>32</sup> has described a similar pleomorphic coccus in acute epidemic poliomyelitis. Crookshank<sup>33</sup> has pointed out the resemblance between Rosenow's coccus, the organism found by Rajchman in encephalitis lethargica, and Donaldson's organism. Further, he points out that Rajchman from his pure cultures of "Rosenow" produced under strict anaerobiosis a free growth of minute bodies resembling Flexner's "globoid bodies" and also those obtained by Rose Bradford, Bashford and Wilson<sup>29</sup> from the filtrable virus in influenza.

The sugar reactions of various cocci isolated in influenza are given in Table V.

TABLE V.

Organisms.	Morphology.	Glucose.	Lactose.	Saccharose.	Maltose.	Mannite.	Lavulose.	Milk.
Donaldson's "D" organism.	Pleomorphic coccid and bacillary forms.	A.	A.	A.	A.	—	—	A.
<i>Diplococcus mucosus</i> (Stephan).	"	A.	—	A.	A.	—	—	A.C
<i>Diplococcus pandemicus</i> (Segale).	Gram + pairs and short chains of cocci	A.	A.	—	A.	—	—	—

A. = Acid. A.C = Acid clot.

The result of these investigations is that it has been demonstrated that in this epidemic a diplococcus, often growing in chains, has been present very constantly in the sputum, occasionally in blood, naso-pharyngeal swabs, and post-mortem material. The coccus is pleomorphic and variable in Gram staining, and possibly also in its sugar reactions.

Evidence that this pleomorphic coccus is the actual causative agent in influenza is at present incomplete.

#### Bacteriological Investigations.

I did not begin active laboratory work in connexion with influenza until the commencement of January, 1919. At that period I was impressed by two facts—the relative infrequency with which Pfeiffer's bacillus was being found, and the significance of the observations of Donaldson<sup>31</sup> on his pleomorphic organism "D" and its possible relation to the filtrable virus obtained by Nicolle<sup>27</sup> and Gibson.<sup>24</sup> Further, Captain H. J. B. Fry, R.A.M.C. (T.), pathologist at No. — General Hospital, had obtained results which suggested the occurrence of two other stages in the life-history of the parasite—a large spore stage and a hyphal stage. The results I am about to describe are those of my own experiments conducted in the laboratory of No. — General Hospital, which was then in the charge of Captain Fry. Much work has been done by Captain Fry alone, both before and after I commenced my investigations, and he has already sent in for publication a preliminary note on his findings. I therefore make no claim for originality, and the deductions drawn are merely the sequence of the deductions of previous observers.

**Examination of sputum.**—Sputum was collected in sterile Petri dishes and examined shortly after expectoration. Films were made and stained by Gram's method, carbol-fuchsin being used as a counter stain. In certain cases the sputum was examined daily throughout the disease; in others only one examination was made. A large number of sputa have thus been looked at. Examination of these films shows the presence of a variety of organisms, and it is suggested that certain of these are stages in the life-history of a mycotic parasite—that, in other words, influenza is a mycosis.

The evidence that is forthcoming to support this view will be detailed below, but a preliminary statement will help to unify the bacteriological findings and enable them to be considered in what is believed to be their true relations one to another.

Film preparations made from material from two sources show most, if not all, the different stages of the parasite; these sources are the lungs and the intestines. Thus sputum in cases of influenzal bronchitis or broncho-pneumonia, and faeces in cases of influenzal enteritis, yield films which when stained by Gram's method show the following forms:—

1. *Hyphae*, septate and branching.—In their substance large round or oval spores 4 to 5  $\mu$  in diameter may be formed, or smaller spores or smaller coccal bodies which occur in diplococcal and streptococcal forms. Further small exospores may be seen attached to and shed from their exterior. The finer filaments may septate into bacillary forms.

2. *Large spores* may occur singly or in groups. They may be round, oval, or elongated, and shaped like Zeppelins or spindles. Generally retaining Gram's stain with avidity, in some cases they are Gram-negative, or have a Gram-positive centre with a Gram-negative periphery. Further, they may be frankly Gram-negative, and contain Gram-positive granules. When seen unstained in hanging drop preparation they appear to have a smaller circular body inside the main body. Their size is about 5  $\mu$  in diameter.

1, Hyphae; 2, large spores; 3, coccal clusters; 4, small spores; 5, tetrads; 6, mulberry masses; 7, chains of cocci in hyphae; 8, bacilli.

3. *Coccal clusters*.—These consist of aggregations of small cocci, 0.5 to 1  $\mu$  in diameter, in circular masses. Generally they are Gram-negative, and contain towards the centre one or more larger Gram-positive coccal forms. They are believed to be derived from the large spores.

4. *Small spores*.—These are circular Gram-positive or negative bodies, about 2  $\mu$  in diameter. They may divide and form—

5. *Tetrads*, which are almost invariably intensely Gram-positive, or

6. *Mulberry masses*, which are knobby agglomerations of Gram-positive bodies, formed by incomplete fission of the small spores.

7. *Chains of cocci*.—These are often diplococci or diplostreptococci, and may be small with flattened opposed surfaces, and variable in Gram staining. Four, six, eight, or ten occur in a chain, or they may be larger and ovoid, forming a *Streptococcus maximus*, and not then tending to vary in Gram's stain, all the elements being Gram-positive.

8. *Bacilli*.—Large Gram-positive or Gram-negative rods, 2 to 3  $\mu$  in length and 0.5  $\mu$  in breadth. Smaller Gram-positive or negative bacilli, down to minute Gram-negative bacilli, morphologically resembling that of Pfeiffer: intermediate cocco-bacillary forms also occur.

The connexion between these stages is put forward diagrammatically (as shown above).

Returning now to the actual examination, and dealing first with *sputum*; in all cases in which films were made from cases of influenza a large number of the above stages were seen, the commonest being coccal clusters, hyphae, large spores, and diplostreptococci. Pfeiffer-like bacilli were not often noticed.

Dealing now with special cases, that of Case 124, which proved fatal on the sixteenth day of the disease, showed on the eighth day bright green purulent sputum. This contained groups of Gram-positive and Gram-negative large spores in great numbers, the only other organism being small Gram-negative bacilli in chains, and Gram-positive and Gram-negative minute cocci in clusters. (Fig. 1A.) The sputum of the next day showed many large Gram-negative spores, many minute Gram-negative cocci, and a few Gram-negative hyphal threads. This was cultured on to trypsinised serum-glucose agar and showed an apparently pure growth in 18 hours of minute circular, slightly raised, transparent colonies—a little iridescent by transmitted light, and about 0.5 mm. in diameter.

Examination of a film made from a single colony showed small Gram-positive cocci and a few Gram-negative bacilli, and Gram-negative large spores with Gram-positive cocci attached to their periphery. This culture was kept 3 days at 37° C. and 13 days at room temperature, and then showed a thick, uniform, diffuse, white heaped-up growth, glistening strongly by reflected light. A film showed this to be an almost pure culture of Gram-positive large spores, together with some Gram-negative large spores containing Gram-positive granules—the other elements being scanty and consisting of some small Gram-positive and negative cocci, and a Gram-negative filament with Gram-positive exospores. (Fig. 1B.) Subculture on agar for 20 hours yielded a diffuse growth of minute pin-point grey translucent colonies, becoming confluent. Single colony examinations showed many Gram-positive large spores of varying shapes, a few small Gram-positive cocci, and one or two Gram-negative bacilli.

On further subculture the large spores were obtained practically pure, and on hanging drop in 2 per cent. glucose broth grew out at 37° C. in 16 days into branching filaments, containing and shedding the small coccal forms and having a variable Gram reaction.

A further 10 cultures were made from sputum; they were planted either with or without preliminary washing in sterile saline on the following media: (1) Matthews's medium<sup>8</sup>; (2) Levinthal's medium<sup>23</sup>; (3) Löffler's serum medium; (4) tryptic serum-glucose agar; (5) agar; (6) 1/500,000 brilliant green agar.

Now, although Matthews's medium and Levinthal's medium are described as being especially suitable for the isolation of Pfeiffer's bacillus, in no case could I isolate it. I obtained single colonies which showed minute polar

staining, non-motile, Gram-negative bacilli, growing in chains and resembling Pfeiffer, but the colonies individually were never pure. They contained one or two Gram-positive coccal elements, and would grow on subculture on agar. Further, on subculture the Pfeiffer-like bacilli would often disappear—even when the subculture was made in Matthews's medium, and Gram-positive and negative coccal forms grow.

In another instance, in a case of broncho-pneumonia, with typical blood-stained sputum, the washed sputum was planted on Matthews's medium. After 24 hours' incubation at 37° C. a growth showing some minute colonies resembling those described for Pfeiffer was seen.

Examination of three of these showed in each case a mixture of Gram-positive cocci and a few Gram-negative bacilli, but no Pfeiffer's colonies were obtained. Case 90, which proved fatal on the fourteenth day of illness, showed on the eleventh day sputum thick, green, and purulent.

In films only Gram-negative, Pfeiffer-like bacilli were seen in enormous numbers, together with a few Gram-negative coccal clusters. It was planted on Matthews's medium and on tryptic serum-glucose agar. After incubation at 37° C. for 24 hours, examination of individual colonies showed no Pfeiffer or even Pfeiffer-like bacilli—thus one single colony contained Gram-positive diplostreptococci, Gram-

negative cocci, Gram-positive large spores, and minute Gram-positive cocci.

The results of the sputum examinations were therefore as follows:—

*Films* showed organisms which appeared diagnostic of influenza—namely, hyphæ, large spores, small spores, coccal clusters and mulberry masses, diplostreptococci.

*Cultures* in no case yielded Pfeiffer's bacillus. A pure culture of large spores was obtained, which grew out into hyphæ, small spores, and coccal forms. Single colonies, even on subculture, were not pure, in that they did not contain only one organism.

An endeavour was then made to determine whether these organisms, as seen in the sputum in every case of influenza, occur in other respiratory diseases. Three cases of pulmonary tuberculosis with tubercle bacilli in the sputum, when stained by Gram's method, showed none of these forms.

Two or three cases of post-anæsthetic bronchitis have been examined with negative results, but the material from a sufficient number of definitely non-influenzal cases has not been available to make a certain statement on this point, which appears to be of considerable importance.

*Examination of feces.*—Six cases of influenza that had attacks of acute enteritis during their illness were examined bacteriologically. They were passing liquid motions containing bright red blood. Specimens were collected on sterile swabs, and direct films stained by Gram's method. In all cases large spores, Gram-positive and Gram-negative, were seen. In addition there were coccal clusters of Gram-negative and Gram-positive elements, hyphal filaments,

emulsion of the agar slope culture was made and found to give no agglutination in dilutions of 1/25 to 1/250 of the patient's serum taken during convalescence on the twelfth day of illness.

The organism appears to resemble closely the pneumobacillus of Friedländer, but did not form a nail-headed growth in slab cultures in gelatin. Further, it appeared pleomorphic, for on incubating the broth culture for 20 days at 37° C. Gram-positive large spores, small Gram-positive cocci, and minute Gram-negative cocci were found.

*Urine cultures.*—It is a comparatively common occurrence to find albumin, blood cells, or even casts present for a few days in the urine during an attack of influenza, but I have not seen any publication which describes positive results in urine cultures during the disease.

In my series seven cases of influenza were examined for the presence of organisms in the urine, and of these six were positive, giving a percentage of 86 per cent. positive results.

I performed these experiments at the suggestion of Captain Fry, who had previously obtained positive results in some cases. In every case the urine was drawn off under the most rigidly aseptic conditions by catheter into a sterile test-tube. 5 c.cm. were transferred to a sterile centrifuge tube and centrifuged at high speed for 10 to 15 minutes. By means of a sterile pipette films were made from the deposit, and a broth tube and agar slope or Löffler slope were also inoculated. The urine and the cultures were then incubated at 37° C.

The results obtained may be expressed in Table VI.

TABLE VI.

No. of case.	Day of disease, temperature, and nature of case.	Urine deposit.	Duration of incubation of urine necessary before obtaining growth on subculture.	Primary subculture.	Later subcultures.
81	5th day. T. 98° to 99° F. Bronchitis.	No albumin, no cells, no casts. G. - bacilli with G. + tips; G. + cocci.	72 hours (Löffler).	G. + cocco-bacilli; G. + cocci; G. - threads.	Pfeiffer-like bacilli. G. + cocci; G. + large spores. Mucin.
83	4th day. T. 100° F. Bronchitis.	No albumin, a few epithelial cells. G. + cocco-bacilli.	Sterile.	Sterile.	Sterile.
85	5th day. T. 102° F. Bronchitis.	Trace of albumin, one or two red and white blood cells, one cast. G. - cocci; G. - bacilli.	48 hours (agar and Löffler).	G. + cocci; G. - cocci; G. - bacilli.	G. + cocci; G. + diplococci; G. + large spores. Mucin.
87	7th day. T. 99° F. Bronchitis.	No albumin, no cells or casts. G. + diplococci; few G. - diplococci.	24 hours (agar and Löffler).	G. + diplococci; G. + tetrads; G. - bacilli.	G. + cocci + small spores.
130	8th day. T. 100° to 101° F. Severe bronchitis.	Albumin present, no cells or casts. G. + small spores; G. - bacilli; G. - bacilli with G. + tips; G. - filaments.	18 hours (broth); 40 hours (agar).	G. + cocci; G. - small spores.	G. + diplostreptococci.
159	6th day. T. 100° F. Severe bronchitis.	No albumin, no cells. G. + large spores; G. - small spores.	Direct (broth).	G. + ovoid diplococcus; G. - hyphæ containing small spores; G. + filaments.	G. + ovoid diplostreptococcus.
170	10th day. T. 100° F. Bronchitis.	Much albumin, many red cells, few white cells. ? G. negative, large spores.	Direct (broth); 18 hours (agar).	G. + small spores; minute G. + diplococci; G. - large spores.	G. + diplostreptococcus. Few G. - cocci.

G. + = Gram +. G. - = Gram -.

diplostreptococci, mulberry masses, and bacilli. In one case (No. 87) a 1/500,000 brilliant green agar plate was inoculated from a saline emulsion of the feces. After 24 hours' incubation at 37° C. small raised, rounded, whitish pin-point colonies were seen.

A film made from one of these showed Gram-negative bacilli of varying lengths and Gram-negative filaments, and one of the filaments contained a Gram-positive spore in its substance. A subculture from this colony on Löffler's serum medium produced in 24 hours at 37° C. a pure culture of Gram-negative bacilli of varying lengths and a few filamentous forms, the culture being a uniform, raised glistening growth, whitish in colour, composed of minute colonies. This was subcultured in broth for 24 hours at 37° C., and produced a uniform turbidity of the medium. A film showed Gram-negative, short, rather plump bacilli, and no filamentous forms. An agar slope was inoculated; after 24 hours at 37° C. the colonies were circular, about 2 mm. in diameter, opaque, and grey.

The sugar reactions of this organism was as follows: Acid and gas were produced in lactose, glucose, mannite, and cane sugar. Milk became acid the first day, and remained acid with clot the second day. Gelatin was not liquefied. It was very slightly motile. A saline

Thus, whereas six out of seven urines gave a positive culture, not one gave a positive culture when placed direct (without previous incubation of the urine) on to a solid medium; but if the urine were incubated at 37° C. for from 18 to 72 hours subcultures were obtained in six cases. The two urines which were also put direct into broth gave a direct growth, but in these cases also the urine had to be incubated before a growth could be obtained on subculture on a solid medium. Further, it will be seen that from urines the following stages have been obtained: hyphæ, large spores, small spores, coccal clusters, tetrads, mulberry masses, diplostreptococci, and Gram-negative bacilli.

The sugar reactions of the cocci obtained from Cases 130, 159, and 170 were determined, and are shown in Table VII.

A control specimen of urine, removed with similar precautions from a healthy individual by catheter, remained sterile during incubation for a week, and would not grow on subculture.

*Blood cultures.*—These were made in 13 cases, and in one case a positive result was obtained, which is equivalent to 7.7 per cent. positive results. In each case the blood was removed by venipuncture, and received direct through a sterile needle with short rubber tube attached into the tubes containing the medium.

170	"	"	"	Acid (late).	"	Nil.	Alk.	Not liquefied.

The media employed were: (1) Broth; (2) 2 per cent. glucose broth; (3) 4 per cent. maltose broth; (4) citrated broth; (5) sterile urine. The tubes contained 5 c.cm. of the medium, and an equal volume of blood was added to each. In two cases the blood was in addition received direct in a sterile tube before subcultures were made, and in one of these there was a positive result, the growth being obtained on serum-glucose agar from the broth subculture which had been incubated six days. Although in the other cases subcultures from the primary culture remained sterile, yet in 11 out of the 12 cases organisms were seen in the primary cultures after incubating for periods varying from 4 to 24 hours. The results are shown in Table VIII. :—

TABLE VIII.—Blood Cultures.

No of case.	Day of disease.	Temperature (Fah.).	Primary culture.	Subculture.
82	6th	99°-100°	G. - rods with G. + tips (broth).	Nil.
83	3rd	101°-102°	G. + granular bacilli; G. - bacilli (broth).	"
83a	4th	101°	Nil (broth).	"
84	5th	99°	G. - bacilli, G. + cocci (citrated broth); G. + small spores (urine).	"
88	8th	103°-104°	G. + small spores; G. + coccobacilli and filaments; minute G. + coccal bodies (broth and glucose broth).	"
89	9th	103°	Large G. + spores and hyphae (glucose broth).	"
90	"	101°-102°	G. + cocci (glucose broth).	"
92	6th	100°-8°	G. - large spores and hyphae (glucose broth).	"
96	9th	101°	G. + diplococci; G. - bacilli; G. + small spores (glucose broth).	"
126	8th	103°	G. - cocci and bacilli; G. - large spores (glucose broth).	"
135	7th	101°-102°	G. - large spores with G. + centre (incubated blood, glucose broth).	G. + diplococci in chains. †
181	4th	103°	G. + large spores and G. + cocci.	Nil.
197	9th	105°	G. - large spores.	"

\* But grew from blood later, when patient was bled.

† Agar and serum-glucose agar.

The subcultures from Case 135 grew equally well on agar and serum-glucose agar, in minute transparent dew-drop colonies, tending to become confluent.

The sugar reactions were as follows: Glucose, acid; lactose, acid; maltose, acid; mannite, nil; cane sugar, nil; salicin, nil; milk, alkaline; gelatin, not liquefied.

It therefore resembles very closely the coccus isolated from the urine in Case 170; the only difference being the late change produced in mannite in the urine coccus.

Primary cultures of blood show the following stages: Large spores, small spores, hyphae, cocci in clusters, pairs and diplostreptococcal form, Gram-negative bacilli and Gram-negative bacilli with Gram-positive tips; and minute coccal forms which appear to be liberated from large spores, and which are approaching the limits of microscopic visibility.

There is difficulty in obtaining growth on subculture, but in one case the coccal form grew out, and had the same morphological appearance as that seen in urine and sputum, although the sugar reactions varied slightly.

#### Pleural Effusions.

Six cases were examined bacteriologically. Cells were scanty, a few small lymphocytes and polymorphonuclears being found in the deposit after centrifugalisation. Direct films showed a few Gram-negative bacilli, and in one case

a pleomorphic variably Gram-staining organism of diplostreptococcal type. In no case was growth obtained on subculture. The organisms described above are illustrated in the accompanying figures.

1. *Large spores*.—In A, sputum film; B, sputum culture; C, blood culture; D, urine; E, faeces.

2. *Hyphae*.—In A, sputum film; B, faeces; C, culture from large spores.

3. *Coccal clusters and mulberry masses*.—In A, sputum film; B, faeces; C, urine.

4. *Tetrads; cocci, bacilli*.—In A, sputum film; B, sputum culture; C, faeces; D, urine film; E, urine culture; F, blood culture.

#### Conclusions from Bacteriological Examinations.

Examination of material obtained from patients suffering from influenza has shown the presence of a mycotic organism.

It is possible that the disease is a mycosis—not necessarily in all cases a bronchomycosis, but perhaps in some an enteromycosis.

The originality of these findings belongs to Captain Fry, with whom I have performed experiments on animal inoculation and examination of material obtained post mortem in man.

Although the results obtained do not justify an assertion that influenza is a mycotic infection, they appear to demonstrate the fact that such an organism is present during the disease, and afford a means of unifying the seemingly discordant results that have been obtained by other workers.

## SANATORIUM TREATMENT AND MILITARY SERVICE:

### AN ANALYSIS OF 47 CASES.

By EDWARD E. PREST, M.A., M.D. CANTAB.,

MEDICAL SUPERINTENDENT, AYRSHIRE SANATORIUM; CONSULTING PHYSICIAN, AYRSHIRE COUNTY TUBERCULOSIS COMMITTEE.

The following account of the adventures of a number of patients who had served in the various services during the war, after being treated in a sanatorium, may be of interest at the present time. It must not be supposed that this is the best which might be expected if the cases had been treated at an earlier date, for many of these cases were not very favourable, and in many symptoms had existed for prolonged periods before undergoing treatment, and the stage stated does not indicate necessarily the duration of symptoms, as some cases advance rapidly in a short time, whilst others go on for long periods before much apparent destruction has taken place. Most of these cases were volunteers in the true sense, for most of them could have procured exemption by obtaining a certificate. They did not ask my advice before enlisting; in some cases I should have attempted to dissuade them, and a number ought certainly to have been rejected. I think, however, it goes to show that were cases treated at sanatoriums as soon as symptoms became recognisable and were persistent, it would become unnecessary to reject

Pr. or Ab. = Presence (+) or absence (-) of tubercle bacilli: (1) on admission; (2) on discharge.

Stage.	Year of admission.	Pr. or Ab.	Progress and particulars.
		(1) (2)	
1 1st	1907	-	Enlisted 1915; 4 years France; demob., well and working at his trade.
2 1st	1909	-	Severely wounded, left to die; almost complete recovery from wounds, working at his old trade for two years.
3 2nd	1909	+	Still in the Army, well.
4 1st	1909	-	Untraced; probably should not have been taken.
5 2nd	1909	+	Engineer, Mercantile Marine; torpedoed Feb., 1917, 350 miles from land, 15 hrs. in open boat, no worse; killed by torpedo, April, 1917.
6 1st*	1910	-	Should not have been enlisted; demob.; working at his old trade.
7 2nd	1910	+	Three years France, sergeant; demob., well, working at his old trade.
8 1st	1910	-	Served in Salonika and India; demob.; working at his old trade.
9 2nd	1910	+	Two years in Army; demob., well, returned to his old trade.
10 1st	1910	+	Enlisted at latter end of war; demob. against his will, working at his old trade.
11 2nd	1910	(a)	Served in France until very severely gassed; readmitted; well, working at his old trade.
12 1st*	1910	-	Served from 1914 in Egypt and France, wounded; demob., working at his old trade.
13 1st	1911	-	Enlisted under age; discharged, working at his old trade.
14 2nd	1911	+	(b) Another affection whilst in sanatorium, kept him in bed for weeks; served through war till severely wounded; well.
15 2nd	1911	+	Served some years in France; sergeant; readmitted; well.
16 1st	1911	-	Served in Egypt; demob., well.
17 2nd	1911	-	Served four years on home service; demob., well, and working at his old trade.
18 2nd	1911	-	Enlisted 1914. Very severe y wounded in France; well except for results of injuries.
19 1st	1912	-	Served from beginning of war, wounded twice, Egypt and France; well.
20 2nd	1912	+	Enlisted 1914. Wounded in France. Readmitted 1917; died in a few days from influenza.
21 2nd	1912	+	Enlisted 1914, served in Egypt, broke down after 2 years' service; readmitted, worked for a time; died from acute tuberculosis after short illness.
22 1st	1912	-	Still in Army, well.
23 1st	1913	+	Reservist, compelled to go to France; broke down. At present working.
24 1st	1913	+	(b) Served throughout war in Navy. Torpedoed, 1917; 4 days in open boat. Malaria whilst in Red Sea, Jan., 1919, still in Navy and quite well.
25 1st	1913	-	Enlisted 1915; 1-corporal; at present demob., well, and working at his old trade.
26 1st	1913	-	Served in Egypt, Dardanelles, and France; demob., well, working at his old trade.
27 1st	1913	-	(c) Enlisted early in war, corporal, gassed and badly wounded; demob., well but for wound trouble.
28 1st	1913	-	Served at home; demob., working at his old trade.
29 2nd	1914	-	Fought through earlier part of war in France, last heard of in military hospital.
30 2nd	1914	-	Enlisted 1916, still in France, well.
31 3rd	1914	-	Fought in France, broke down; in 1917 sent to Egypt, ship torpedoed, 4 hours in open boat; demob., well, and working at his old trade.
32 1st	1914	-	Still in Army, well.
33 3rd	1914	-	Enlisted April, 1916; blown up and buried; readmitted 1917; died from pulm. tuberculosis two days after leaving sanatorium.
34 1st	1914	-	Enlisted 1917, corporal; served in France. Demob. Jan., 1919. In excellent health.
35 2nd	1914	-	Served four years in Army; demob., well, and working at his old trade.
36 2nd	1914	-	Enlisted when not feeling well; died after two operations in military hospital. Advised to return to sanatorium instead of going into Army.
37 2nd	1914	-	Enlisted 1914; for 14 months in thickest of fighting in France; died of wounds in 1916.
38 2nd	1914	-	Enlisted 1915, corporal; after much fighting in France very severely wounded; now demob. and working at his old trade.
39 1st	1914	-	Enlisted at 18, served in Egypt and France; well.
40 2nd	1914	-	Enlisted in 1915, was five months in Army, discharged for other illness; working at his old trade ever since.
41 1st	1915	-	Remained in sanatorium a short time, returned to Army, soon after discharged; unsatisfactory case. Working when last heard of.
42 2nd	1915	+	Killed in France, 1917.
43 2nd	1915	-	Conscripted, should not have been taken; soon afterwards discharged, now labouring.
44 3rd†	1916	+	Conscripted, should not have been taken. Died in Army from influenza (?) 1918.
45 2nd	1916	-	Conscripted; keen to go, should not have been taken; served successfully for some months; broke down after influenza; readmitted.
46 2nd	1917	-	Only in Army a short time; readmitted and is now well; he could only be treated for 3 months when first in sanatorium.
47 1st	1915	-	Enlisted 1917; gassed in France; in hospital some months; quite well, working at his old trade.

\* Acute. † Laryngeal. (a) Present before admission. (b) No sputum on discharge. (c) Reacted to tuberculin under treatment.

men on the ground that they had been in a sanatorium, and it follows from this that under ordinary peace conditions such patients would return to their former manner of life and old avocations. It should, of course, be understood that if passed as medically fit the country would have to take complete responsibility for their condition if they subsequently broke down. Had all sanatoriums spent their energies from their inception in treating early cases they might easily have produced a division of excellent soldiers; as it is, the majority of the patients treated in sanatoriums are either dead or hopelessly unfit, and are requiring after-care.

#### Analysis of Cases.

Except in certain cases which should not have been enlisted, it will be seen that the expense of treating these men for tuberculosis has not been excessive. All these cases were treated in the Ayrshire Sanatorium. I have only come across one case treated in the Ayrshire hospitals for advanced cases who enlisted, and he apparently made a bet that he would be taken, and he was passed Grade I. and saw some years' service in the East; he was finally invalided out of the Army with tuberculosis, and at the present time he is in fair condition.

The occupations of the above when admitted to the sanatorium were as follows: Coal-miners, 14; labourers, 6; schoolboys, 5; engineers, shop assistants, painters, iron moulders, and railway clerks, 2 of each; groom, bleacher, cabinet maker, iron turner, brass finisher, iron-stone miner, surfaceman, gardener, blacksmith, French polisher, mason, and agricultural labourer, 1 of each. One of these patients became a professional athlete after leaving the sanatorium, and is so engaged at the present time. One held a commission, another was offered a commission, 1 won the military medal, 1 was promoted on the field for valour, 2 were sergeants, and 3 were corporals. Three lost their lives in their country's service, 8 were wounded, 3 gassed, and 1 buried alive. One was discharged from the Army because he was said to be suffering from valvular disease of the heart; he really had heart failure due to excessive fibrosis, and should not have been taken. Another had suffered from caries in the spine; this man did home service right through the war, and is at present working at a laborious occupation. One man was discharged after an anti-enteric inoculation, and he has been working ever since. One was in hospital for some months, supposed to have pneumonia, but from the account he gave of himself he had evidently been suffering from an acute attack of tubercle; this is a mistake which is constantly being made, and is the cause of not a few incorrect death certificates. This man is now at his old work after seeing a good deal more of service. It will be noted that 14 had tubercle bacilli in their sputum, one reacted to tuberculin, and of those in whom bacilli were not found 12 were in the second stage and two in the third.

In closing I may remark that 28 had been in the sanatorium in 1913 or previous years, and had been engaged in their ordinary occupations for some time before war broke out. Finally, I would remark that the sacrifices of these men will not have been made in vain if they teach us that those who have had the misfortune to contract tuberculosis may be worthy of a better fate than to be segregated, but let it be understood there can be no worse place for an uncured tuberculous patient in war time than the Army.

LONDON HOSPITAL: OLD STUDENTS' DINNER.—The old students' dinner will be held on Thursday, Oct. 2nd, at Princes' Restaurant. Sir Bertrand Dawson will preside. This will be the first reunion of old students since the outbreak of the war. Application for tickets should be made to one of the honorary secretaries, Mr. Hunter Tod, 11, Upper Wimpole-street, W. 1, or Dr. Charles H. Miller, 32, Devonshire-place, W. 1.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—The following elections to scholarships have been made:—Burney Yeo scholarships: J. W. Hirst, Gonville and Caius College, Cambridge; C. F. T. East, New College, Oxford. Senior Scholarship and Todd prize: E. A. L. Crichtlow, M.R.C.S., L.R.C.P. Jelf medal: H. Kamal, M.B., B.S., M.R.C.S., L.R.C.P. Tanner prize: Miss D. E. P. Jolly.

## THE INCIDENCE OF TUBERCULOSIS AMONGST ASYLUM PATIENTS.

BY FRANK ASHBY ELKINS, M.D. EDIN.,  
MEDICAL SUPERINTENDENT, METROPOLITAN ASYLUM, LEAVESDEN;  
AND

H. HYSLOP THOMSON, M.D. GLASG., D.P.H.,  
COUNTY MEDICAL OFFICER OF HEALTH AND COUNTY TUBERCULOSIS  
OFFICER FOR HERTFORDSHIRE.

SINCE the commencement of the war there has been a marked increase in the prevalence of, and death-rate from, pulmonary tuberculosis. During 1917 the crude death-rate from this disease in England and Wales amongst civilians was 1250 per million population, compared with 1178 for 1916 and 1034 for 1912-14. The cause of this increase is to be attributed to the existence of conditions directly arising from the war which have impaired our resistance to attacks by the tubercle bacillus and which have favoured the spread of infection. Such conditions are to be found in prolonged mental anxiety and worry, physical exhaustion, depletion of the normal dietary, increase of the ratio of population per house, and departure generally from the normal pre-war standard of living. This increase in the incidence of pulmonary tuberculosis provides one significant lesson. It emphasises the fact that even under pre-war conditions the national reserve of resistance to attack by the tubercle bacillus was small and that any degree of security and the prospect of finally controlling tuberculosis can never be attained until the national reserve of resistance has been materially increased.

The increase in the incidence of pulmonary tuberculosis, which has been a feature of the last four years, is especially characteristic of the mentally abnormal population. Since 1914 there has been an increase of 41 per cent. in the deaths from tuberculosis in lunatic asylums. One of us has had the opportunity of studying tuberculosis amongst the insane for a period of over 30 years, and the marked increase in the death-rate from this disease since the commencement of the war amongst the inmates of a large asylum has been a cause of much thought and anxiety. It is obvious that the reserve of resistance to tuberculous infection in the insane and low-grade mentally defective person reaches a very low standard. In the following table are given the death-rates from tuberculosis during the last 20 years amongst the inmates of a large metropolitan asylum.

Death-rates from Tuberculosis during the last 20 years amongst the Inmates of a Metropolitan Asylum.

Year.	Average No. patients resident.	Deaths from all causes.	Mortality from tubercle—		Year.	Average No. patients resident.	Deaths from all causes.	Mortality from tubercle—	
			Deaths.	Rate per 1000				Deaths.	Rate per 1000
1898	1986	194	55	27.6	1909	2069	210	70	33.8
1899	1952	250	73	37.4	1910	1911	120	31	16.2
1900	1905	310	104	54.6	1911	2049	144	38	18.5
1901	1772	164	67	37.8	1912	2068	129	41	19.8
1902	1768	134	43	23.8	1913	2051	197	59	29.0
1903	1752	131	34	19.4	1914	2099	172	42	20.0
1904	1751	158	53	30.2	1915	2045	240	70	34.2
1905	1776	126	44	24.7	1916	2041	283	102	49.9
1906	1782	127	40	22.4	1917	1941	459	141	72.6
1907	1819	151	37	20.3	1918	1769	542	208	117.6
1908	1920	156	39	20.3					

Note.—From the year 1900 onwards the diagnosis has been assured by post-mortem examination in more than 90 per cent. of cases.

From this table it will be seen that the death-rate from tuberculosis in 1914 was 20 per 1000, and that the rate has risen since that year to 117.6 per 1000 for 1918. The increase in the death-rate from tuberculosis amongst the inmates of asylums since the commencement of the war is remarkable, and is referred to by the Registrar-General in his annual report for 1917. In that report it is stated that 12 out of 97 county and county borough asylums were evacuated during the war in order that they might be devoted to military purposes, and this is stated by the Board

of Control to have led to some degree of overcrowding. But, as is pointed out by the Registrar-General, this had much abated in 1917 from what it was in 1915, when the deaths from tuberculosis were far fewer. This fact is borne out by the table given above, for in 1914, when the average number of patients was 2099, the number of deaths from tuberculosis was only 42, whereas in 1918, when the average number of patients was only 1769, the number of deaths from this cause was 208.

### Clinical Features.

One of the features of pulmonary tuberculosis is the variation in type which it presents, and the disease as it is found amongst the mentally abnormal population is a type by itself. In the great majority of cases the classical symptoms of the disease are absent. In walking through a ward reserved for the tuberculous insane one is at once struck by the almost entire absence of coughing. The same applies to sputum; the tuberculous insane patient has little or no expectoration for the twofold reason that the amount of sputum actually produced is less than in normal cases, and that any sputum which may exist is swallowed. Hæmoptysis is a rare symptom. The temperature shows very considerable variation. In certain cases the temperature during the latter stages of the disease presents the usual tuberculous type, but in many cases it is subnormal, even when marked pulmonary disease exists, and it is therefore not to be relied upon as a guide to diagnosis. In the non-tuberculous demented type of patient it is quite usual to have a subnormal temperature which rises to normal when tuberculosis develops. The most significant feature of pulmonary tuberculosis as it exists amongst the insane and mentally defective is the frequency with which gross pulmonary lesions exist without any corresponding physical signs to suggest the existence of such changes. This fact seriously complicates the question of diagnosis and provides room for doubt as to the accuracy of the statistical evidence of the incidence of tuberculosis in asylums, unless such evidence is based on post-mortem findings. The figures given in the present article are, for the most part, based on post-mortem evidence and, therefore, may be accepted as accurately representing the upward trend of asylum tuberculosis since the outbreak of war. The clinical picture of asylum tuberculosis may be briefly described as loss of flesh with progressive muscular wasting and weakness, and the onset of diarrhoea due to abdominal tuberculosis in a large percentage of cases.

### Ætiological Factors.

The high attack-rate and death-rate from tuberculosis amongst the insane are due to fairly well-defined causes, some of which are preventable, others of which it is impossible to control. The first root cause is the lowered tissue resistance to attacks by the tubercle bacillus, which is characteristic of mentally abnormal persons, more especially the lower grade type such as idiots, imbeciles, and the demented. In the Leavesden Asylum the death-rate from tuberculosis has always been high, and one explanation of this high rate is the fertility of the existing soil owing to the low grade and hopeless type of patient which is admitted.

The large majority of patients admitted are in weak or very weak bodily health, and it has been rare to admit a man or woman capable of doing work. The type of case admitted may be gauged from the fact that it includes broken down senile cases, epileptics, demented general paralytics, demented drunkards, mental defectives, chiefly idiots and imbeciles and patients with advanced bodily disease or with serious physical defects. Patients of this type are unable to work or even to walk about. Their life is spent in bed or in sitting on a chair in the ward, with the result that they have shallow respiratory movements and sluggish circulation. This leads to imperfect lymphatic drainage of the lungs and predisposes to tuberculosis.

With reference to the relationship between the mental phase and tuberculosis it is apparent that certain types of mental abnormality exercise a greater influence in impairing the resistance to tuberculosis than others. A certain percentage of senile cases have become tuberculous in the asylum, although this is of rare occurrence outside. Thus of 326 senile cases which died during the five years ending Dec. 31st, 1918, 9 were found to be tuberculous. According to Clouston, general paralytics never develop tuberculosis, but this has not been the experience at the Leavesden

Asylum. It should be mentioned, however, that all the general paralytics admitted to Leavesden Asylum are abnormal and most of them are of the demented type. Of 52 general paralytics dying during the five years ending Dec. 31st, 1918, 16 were found to be suffering from tuberculosis. Clouston also taught that patients with fixed delusions of suspicion and unseen agency always died of tuberculosis, while persons with grandiose delusions never died from this cause. The experience at Leavesden Asylum shows this to be wonderfully true. This fact is of interest and importance, as it sheds a suggestive light upon the possible ætiological relationship between the mental standard and capacity for muscular movement and tuberculosis.

The second important ætiological factor in the high death-rate from tuberculosis amongst the insane is contact infection. All the available clinical evidence is in favour of contact infection. It is true that insane tuberculous patients have rarely any expectoration, and therefore the medium of infection is obviously not sputum. The frequency of intestinal disease and the extent to which the hands, clothes, bed clothes, &c., are contaminated by faecal matter point to the disease being conveyed through the medium of infected excreta. The following facts clearly indicate that many of the patients dying from tuberculosis have contracted the disease while resident in the asylum:—

	Male.	Female.	Total.
Patients found suffering from tuberculosis on admission during five years ending 1918 ...	31	12	43
Length of residence of patients dying from tuberculosis during 1918:—Under 1 year ...	18	8	26
" 5 years ...	58	11	69
" 10 " ...	45	13	58
" 20 " ...	30	6	36
Over 20 " ...	17	2	19
Deaths from tuberculosis during 1918:—			
Tuberculosis (primary) ...	150	36	186
" (secondary) ...	18	4	22
	168	40	208

Closely connected with the two primary ætiological factors is the question of the ventilation and heating of the wards. Generally speaking, the ventilation and air space provided are not sufficient to exercise any favourable influence in combating the marked predisposition on the part of mentally abnormal persons to the development of tuberculosis. While an abnormally low tissue resistance and the existence of contact infection are to be regarded as the primary causes of the high incidence of tuberculosis amongst the inmates of asylums compared with the mentally normal population, other factors have to be considered which are responsible for the marked increase which has resulted since the outbreak of war. The first and most important of these was the interference with the standard of feeding, more especially with regard to the amount of fats and sugar. Insane people require a diet rich in fats if their resistance to tuberculosis is to be maintained at a satisfactory level. Other contributory causes are the occurrence of outbreaks of influenza and pneumonia during 1917, and more especially in 1918, the weaker state of the patients admitted during the period referred to, the serious depletion of the skilled staff experienced in the management of the insane sick and the methods of prevention of disease, and the difficulty experienced in maintaining the cleanliness of the wards by painting and other means. The experience of the past four years has emphasised how extremely sensitive is the tuberculosis index of the insane to unfavourable conditions.

#### *The Diagnosis of Tuberculosis amongst the Insane.*

The control of tuberculosis depends upon early recognition of the disease. The diagnosis of pulmonary tuberculosis as it is to be found amongst insane persons is a clinical problem of peculiar difficulty. In the majority of cases the disease develops and progresses without presenting any definite symptoms or physical signs, and it is not until the condition is revealed by post-mortem examination that the diagnosis of tuberculosis can be accurately made. As has been previously stated, the figures given in the present paper are based on post-mortem findings, and they may therefore be accepted as accurately representing the increase in the death-rate from tuberculosis in the lower grade of the mentally abnormal population during the war.

The most frequent and reliable indication of tuberculosis in the insane is progressive loss of weight with progressive muscular asthenia. The downward trend will, therefore, be speedily observed if all patients in asylums are carefully and regularly weighed. The next important indication is the onset of chronic diarrhoea, more especially if this follows a period of falling weight and failing strength. Conclusive evidence will be obtained by the bacteriological examination and the finding of the tubercle bacillus. Indeed, the more frequent examination of the excreta for tubercle bacilli would be a great aid to diagnosis and would, undoubtedly, reveal the fact that amongst the tuberculous insane the presence of the bacillus in the excreta is high compared with that in the tuberculous sane. The X ray examination of the chest would be of value in clearing up the diagnosis in certain types of cases, although its application might not always be an easy matter. The extent to which the various grades of tuberculous insane patients react to tuberculin, especially the cuti-reaction, is worthy of further investigation, but without such investigation it cannot be relied upon as of any assistance in confirming the diagnosis of tuberculosis. The question of diagnosis may be summed up by the statement that the majority of low-grade insane patients who die from wasting or chronic diarrhoea will be found on post-mortem examination to have been suffering from tuberculosis.

#### *Prevention and Treatment.*

In considering the measures to be adopted to prevent the spread of tuberculosis amongst the insane consideration at the onset must be given to the fact that we are dealing with a type of individual peculiarly susceptible to the development of the disease. It is necessary, therefore, that prophylactic measures should be directed towards maintaining the resistance of the insane patients to tuberculosis at as high a level as possible, and, secondly, to securing the segregation of tuberculous cases or of suspected tuberculous cases as early as is practicable so as to prevent the spread of infection. The resistance of the insane person to tuberculosis during residence in an asylum chiefly depends upon four factors—viz., exercise, ventilation, warmth, and the quantity and character of the diet. Physical exercise, or rather the lack of it, has a direct influence on the capacity of the body to resist tuberculosis, but the physical condition of many insane patients of the low-grade type precludes the possibility of any regular form of physical exercise. The amount of air space per non-tuberculous patient is laid down by the Local Government Board or the Board of Control, but it is obvious that, in view of the striking proclivity of the insane person to develop tuberculosis under certain conditions of asylum life, the amount of air space, and especially the extent of floor space, should be increased. Efficient ventilation with uniform efficient heating, conforming to some extent to a modified open-air regime, would appear to be necessary. The insane person, especially of the lower grade, is very sensitive to changes of temperature and has generally a poor circulation, and while a frequent change of air is essential a sustained uniform temperature is also necessary. A generous dietary with a liberal allowance of fats and sugar is of primary importance in raising resistance to tuberculosis. In common with the rest of the population the inmates of asylums have suffered during 1918 from interference with the normal scale of diet, and the adverse influence of the conditions arising from war would undoubtedly show itself earlier amongst persons of a mentally abnormal type.

With regard to treatment this consists for the most part of segregation in sanatorium blocks with a view to prophylaxis. It is extremely doubtful if the onward progress of tuberculosis to a fatal termination can be definitely arrested in a hopelessly insane or mentally defective person, although the progress of the disease may be very slow. Two special types of sanatorium wards should be provided, one for early cases immediately the disease is diagnosed and for suspected cases, and the other for advanced cases, especially those cases with evidence of intestinal tuberculosis. Cod-liver oil or one of its preparations in combination with creosote should be administered as a method of routine treatment. The development of tuberculosis in an insane person presents a tragic picture, and to visit a tuberculosis ward in a large asylum is an experience not easily forgotten. The question may, no doubt, be asked if it serves any useful or even

humanitarian purpose to endeavour to prolong the life of the tuberculous insane person. If this question were truthfully answered from the point of view of the economic value of the tuberculous insane, it would be answered in the negative, but as the aim of all medical effort is to relieve suffering and prolong life the insane person who develops tuberculosis must receive his due share of care and treatment.

#### Conclusions.

The conclusions to be drawn from a study of the incidence of tuberculosis amongst asylum patients are as follows:—

1. That the mentally abnormal person is, generally speaking, more liable to develop tuberculosis than the individual who is mentally normal.
2. That this liability is primarily due to predisposition dependent upon the mental condition.
3. That the determining factor in the spread of tuberculosis amongst the asylum patients is contact infection.
4. That contact infection amongst the mentally abnormal is frequently due to infected excreta.
5. That the increase in the prevalence of tuberculosis amongst asylum patients since the commencement of the war is due to the influence of a number of well-recognised factors arising from the war.
6. That in view of the extreme susceptibility on the part of asylum patients to develop tuberculosis it is essential that increased efforts should be made to provide such conditions of asylum life as will tend to counteract such susceptibility.

## THE PRIMARY TOXIC EFFECT OF NEOSALVARSAN.

BY PROFESSOR K. PETRÉN.

(From the Intern. Clinic of the University of Lund, Sweden.)

It has been difficult from clinical observations to decide the question, what toxic effects salvarsan produces. We know well that a very great number of observations have been published in which morbid symptoms have occurred after the injection of salvarsan; these symptoms have often been of a very serious character, and Matzenauer reported in 1916 that about 200 fatal cases of intoxication by salvarsan have been published. The symptoms which have been observed as a consequence of the injection of salvarsan have been very various in the different cases; one can, however, say that they all are localised to the nervous system, but otherwise they are described as very different.

#### A "Toxic Storm."

As regards the causes of the morbid symptoms from the nervous system which we can observe after injection of salvarsan, it is generally recognised that one must always take into consideration the possibility that they may be a consequence of the biological interaction between the human organism and the micro-organisms of syphilis—as the experience of the effects of salvarsan has almost exclusively been obtained from observations of patients suffering from syphilis. Many authors have accepted the suggestion that these symptoms from the nervous system, to a very great extent, are due to a "toxic storm"—that is to say, that they suppose a very great number of the micro-organisms of syphilis have been suddenly killed through the effects of salvarsan, which has resulted in a large amount of toxin suddenly becoming free in the blood.

The grounds which speak for such an interpretation of the salvarsan poisoning are, indeed, very strong. As a consequence, we can never come to very definite conclusions as to what are the real toxic effects of salvarsan itself, so long as our experience is confined to patients suffering from syphilis.

#### Neosalvarsan in Influenza-pneumonia.

During the great epidemic of influenza from which every country in the world has suffered during the last year I have had the opportunity of observing the effects of the injection of salvarsan in individuals not suffering from syphilis, as I have tried to treat the influenza-pneumonia with neosalvarsan. In this paper I shall not enter upon the question as to the effects of this treatment on the pneumonia itself. (I hope that I shall find occasion shortly in another medical paper in the English language to treat of this question among a

number of others relating to my experience of influenza-pneumonia.) Here I will only speak of the toxic effect which I have observed as a consequence of the injection of (neo) salvarsan.

In a great number of cases of influenza-pneumonia (about 140) we have given injections of neosalvarsan. In almost every case we injected 0.60 g. (in my first cases only we tried a smaller dose), but having seen no harmful effect follow these smaller doses we had at once progressed to the doses of 0.60, and thereafter regularly continued with the large doses.

In by far the greater number of cases we have not seen any toxic effect whatever. In some few cases, however, we have seen a special effect of the injection, inasmuch as the injection has been followed by vomiting. In some of these cases the vomiting occurred only once; in other cases two or three times, or perhaps sometimes even oftener. This pathological occurrence has quite regularly shown the following characters. The vomiting has appeared during the first 24 hours following the injection—only during this period and never later. The patients have not shown any other signs of dyspeptic troubles. After the lapse of 24 hours no disturbance of the stomach has occurred. Practically all the patients suffering from influenza-pneumonia—and I lay special stress upon this—have been treated with digitalis, either with drug or with digitol (a preparation which approximately corresponds to digalen). When I first saw these cases of vomiting I did not venture to give them digitalis for the next few days, but after having found that the patients to whom I had given digitalis after two or three days tolerated it with no more difficulty than other patients, I began later to give even these patients digitalis in the cases with vomiting, when the first day had passed, in other cases also during the first 24 hours after the injection.

Vomiting after the injection of salvarsan we have seen in a great number of cases of pneumonia among women. For a time I did not observe the occurrence among men, but later I saw it in four cases of men; for three of these cases the body weight was determined 53 kg. (19 years), 53.5 kg. (28 years), and 57 kg. (17 years); the fourth patient was a man of 24 years and was not a person of great weight. Otherwise we have not seen the least toxic trouble after the injection of neosalvarsan. We have never seen albuminuria when the patients had not shown it before the injection, and in those cases where they had albuminuria before the injection we have never observed that it had increased as a consequence of the injection. Also the microscopical examination of the urine has never shown an increase of the sediment as a consequence of the injection. We have never seen headache, vertigo, or other symptoms from the nervous system—with exception of the vomiting—after the injection.

#### Conclusions.

From the foregoing description we find that the toxic effect after the injection of salvarsan was quite monosymptomatic, and that the only toxic effect, when it occurred at all, followed fixed laws, as its occurrence was limited to a fixed period after the injection and was also to a certain degree dependent on the weight of the individual that had received the injection.

When we take these circumstances into consideration it seems unnecessary to discuss the question where the injected salvarsan exercises its effects, as it is quite manifest that a morbid phenomenon of this regular character and of this short duration (with no exception from the rule that the vomiting occurs *only* during the first 24 hours after the injection) cannot be the consequence of a local effect exercised on the stomach wall, but must be the effect of the poison on the centre of vomiting in the bulb.

In consequence, thanks to the circumstance that my observations on the effect of the injection of salvarsan are uncomplicated, in the sense that they are free from the disturbing influence of the biological effect exercised by salvarsan on the micro-organism of syphilis, and thanks to the fact that these observations are of sufficiently great number to lead to the deduction that the phenomena produced are governed by certain laws, we come to the conclusion that the first toxic effect of salvarsan (neosalvarsan) on man can be demonstrated with the certainty of an experiment on animals, and that this toxic effect consists in a strictly elective effect produced exclusively on the centre of vomiting in the medulla oblongata.

# FURTHER REPORT ON THE TREATMENT OF SCIATICA

BY RADIANT HEAT AND STATIC WAVES.

BY JOHN J. GRACE, F.R.C.S. ENG.,

LATE MEDICAL OFFICER IN CHARGE OF THE ELECTRO-THERAPEUTIC  
DEPARTMENT, MANOR HOUSE ORTHOPEDIC HOSPITAL.

SOME years ago I published<sup>1</sup> a short report on the treatment of sciatica by radiant heat and the static wave current. In the interval I have treated some 70 cases, and the results obtained are instructive.

So far as has been possible I have differentiated between sciatica and pain in the sciatic distribution due to osteoarthritis of the hip-joint, or of the sacro-iliac-joint, but this distinction is not always possible, and perhaps some of the

unrelieved cases are of this nature. Of the 70 treated, 59 were cured or relieved of the pain to such a degree that they could pursue their usual avocations in comfort. If it be taken into consideration that I do not see mild or early cases of sciatica, practically all being referred cases in which other forms of treatment have failed, I think the results shown in the table are very good. The term recovery as used in the table means complete recovery, and "no improvement" is the expression of my opinion. The other terms are taken from the patients.

The treatment is painless, except to those few people to whom all electricity is painful. One of these patients is included in the above list, and though she hated the treatment she persisted to a triumphant, though belated, conclusion. No exposure is involved, though the electrode must be applied to the bare skin, and finally no harm is done in the event of failure.

No. of Case.	Sex.	Age.	Duration.	No. of treatments.	Result.	No. of Case.	Sex.	Age.	Duration.	No. of treatments.	Result.

\* An attack every 3 years for 11 years. † 10 years' history of pain in legs; doubtful osteo-arthritis. N.r., not recorded; S.w., static wave; d., days; w., weeks; m., months; y., years.

## Remarks.

CASE 3.—Relapse during military service.

CASE 5.—Had spent 8 months in bed.

CASE 7.—This case was remarkable for its severity, and though the present attack was of short duration he had had a previous severe and prolonged attack. The usual treatment by the static wave with an electrode 6" x 4" applied over the gluteal region from behind the trochanter up towards the sacrum having failed to relieve, I examined the prostate, which was enlarged and tender. Treatment of this with a rectal electrode produced almost immediate relief of the sciatica and markedly reduced the size of the prostate.

CASE 10.—Much better after five, then relapse, and bed for a week. Then six more treatments.

CASE 13.—This man was buried by a shell explosion in 1914. When dug out his thigh was bent back so that his heel was against his back. Pain in the sciatic distribution was constant. He left much improved and free from pain after 16 treatments. The peroneal group of muscles were partially paralysed.

CASE 15.—Was blown up by a shell, and sciatica started immediately. Had had various treatments by electricity and massage before he came to me.

CASE 16.—Had been prisoner of war and had had no treatment.

CASE 18.—Present attack had lasted five months. When first seen he had marked scoliosis. He walked with great difficulty, with the aid of a stick, on the toes of his left foot. Could bear no weight at all on

the leg. Pain very severe and continuous. In six weeks the pain was slight, but the scoliosis remained. Two months later he was quite straight and could walk well.

CASE 20.—Was treated with the X ray only, as the static wave current did not appear to benefit him.

CASE 21.—This patient's sciatica was relieved after 12 treatments. Attention was then directed to lumbago, from which he had suffered for eight years. This, too, got quite well.

CASE 25.—This patient improved steadily for ten treatments; then improvement ceased. The prostate was examined and found slightly enlarged. After four treatments to this he got quite well.

CASE 29.—Patient discontinued treatment.

CASE 31.—Returned 2 years later with recurrence which got well, and again 1 year later.

CASE 37.—Had to return to trenches (very pleased).

CASE 43.—High blood pressure 210 mm. reduced to 165 by auto-condensation.

CASE 47.—Discontinued owing to gout in knee.

CASE 49.—Had to stop treatment. Was a soldier under orders.

CASES 60 and 61.—Same patient, different attacks and sides.

CASE 62.—Got practically well. Went for a long walk, relapsed, and did not again improve.

CASE 65.—Recovered after operation for piles.

CASE 67.—Sciatica followed wound of thigh.

CASE 70.—Discontinued owing to death in family.

Welbeck-street, W.

## INTRAVENOUS INJECTIONS OF ANTIMONIUM TARTARATUM (TARTAR EMETIC) IN BILHARZIASIS.

BY FRANK E. TAYLOR, M.D., M.Sc., F.R.C.S., D.P.H.,

LECTURER ON BACTERIOLOGY, UNIVERSITY OF LONDON, KING'S COLLEGE;  
PATHOLOGIST AND BACTERIOLOGIST TO THE BERMONDSEY  
MILITARY HOSPITAL.

OWING to the recent important advances in our knowledge of bilharziasis much attention has been attracted to this condition. These advances are chiefly due to the work of Leiper, Fairley, and Christopherson.

### Summary of Recent Advances.

In 1915 Leiper<sup>1</sup> worked out the complete cycle of development of the bilharzial worms, giving a connected story of their life-history. He found the non-eyed, bifid-tailed cercariæ characteristic of the genus in two genera of snails, *Bullinus contortus* and *Planorbis boissyi*. These snails were shown to harbour two different species—*Bilharzia hæmatobia*, characterised by a terminal-spined ovum, and *Bilharzia mansoni*, characterised by a lateral-spined ovum.

Fairley's<sup>2,3</sup> work demonstrated how bilharzial parasites and their ova exert a deleterious influence on the tissues of their definitive host, man, mainly by the production of toxins, and not merely mechanically. These toxins call into action cellulohumeral responses which neutralise or limit their activity. As a result immune bodies, including complement-fixing substances, are produced, and a complement-fixation test for bilharziasis has been devised by Fairley comparable to the Wassermann test for syphilis. As antigen an alcoholic extract of the infected livers of snails (*P. boissyi*) was employed. Positive complement-fixation was obtained in a high percentage of cases in man as well as in experimentally infected monkeys. The practical application of this test, Fairley considers, will facilitate the diagnosis of bilharziasis in the early stages of the disease before localising symptoms have developed, and also in estimating the effect of the intravenous administration of drugs on the adult parasites.

Christopherson<sup>4,5</sup> introduced, or independently re-introduced, the administration of intravenous injections of solutions of tartarated antimony (tartar emetic) with success, and claims that this method constitutes a specific cure for the disease. It was the satisfactory results obtained by himself and others by this method in Oriental sore, internal leishmaniasis, and naso-oral leishmaniasis (espundia) as found in the Sudan which induced Christopherson to apply it in bilharziasis, vesical and rectal. This method was commenced by him in the Khartoum Civil Hospital in May, 1917. In September, 1918, he recorded 13 cases of *Schistosomum hæmatobium* treated by this method with apparently complete cure in all the cases, but with relapses in from one to eight months in three cases. As the result of his experience he considers that there is no doubt that antimony given as intravenous injections of tartar emetic considerably interferes with the bilharzia and suspends its activities, even when it does not actually kill. His own opinion, based on the cases treated during the last year, is that antimony (antimony tartrate) is a definite cure for bilharziasis, and that intravenous injections of tartar emetic kill the *Schistosomum hæmatobium* in the blood and render it harmless.

Christopherson's method consisted in giving a course of injections on alternate days for a period of 15 to 30 days, commencing with  $\frac{1}{2}$  gr. dissolved in 6 c.cm. of distilled water and increasing by  $\frac{1}{2}$  gr. up to 2 gr. until a total of 30 gr. have been injected. This amount he considers to be the required killing dose, notwithstanding that all the symptoms of the disease often completely disappear after the first or second injection.

### Series of Cases.

The following ten cases of vesical bilharziasis have recently been treated by this method at the Bermondsey Military Hospital:—

CASE 1.—Pte. C. Admitted to the Bermondsey Military Hospital on Sept. 21st, 1918, having been transferred to England from Egypt for bilharziasis. Blood first noticed in urine in August, 1916. Much blood and many terminal-spined bilharzia ova found in urine. Had 17 injections of tartar emetic intravenously, 29½ gr. being given. Stiffness of neck and shoulder muscles after injection. Discharged well Dec. 12th, 1918.

CASE 2.—Pte. T., aged 27. Admitted Sept. 21st, 1918. Transferred to England from Egypt for bilharziasis. Complained of hæmaturia and abdominal pain in July, 1918, having been stationed in the Fayoum District for 13 months. Albumin, blood, and terminal-spined bilharzia ova found in urine. Ten intravenous injections with a total of 21½ gr. of tartar emetic. No further blood or ova in urine. Discharged well Jan. 20th, 1919.

CASE 3.—Cpl. B., aged 29. Admitted Sept. 21st, 1918, having been transferred to England from Egypt for bilharziasis. Was in the Fayoum District in 1915-16, where he developed hæmaturia with dysuria and hypogastric pain. Albumin, blood, and terminal-spined bilharzia ova found in urine. 27½ gr. tartar emetic injected intravenously. Cough and irritation of the throat after each injection, and vomiting after one injection. Blood and ova not again found in urine. Discharged well Dec. 18th, 1918.

CASE 4.—Spr. S., aged 39. Admitted Sept. 21st, 1918. Went to Egypt December, 1915. Began to pass blood and clots in urine in November, 1916. Complained of hæmaturia and burning sensation at end of micturition with general weakness, wasting, and anæmia. Weight had fallen from 14 st. to 10 st. 7 lb. Terminal-spined bilharzia ova, red blood cells, and a little albumin in urine. 27½ gr. tartar emetic given intravenously in 17 injections. Complained after various injections of irritation in the throat, with tickling cough, nausea, vomiting, diarrhoea, and stiffness of muscles of neck and shoulders. Blood and ova not again found in urine. Discharged well Dec. 4th, 1918.

CASE 5.—Pte. L., aged 22. Admitted Sept. 8th, 1918. Had been in Egypt since April, 1916. Hæmaturia commenced in January, 1917. Bilharzia ova found in urine in Egypt, but not in England, though albumin and blood were present. 22½ gr. tartar emetic injected. Rigor, pyrexia (103°), nausea, vomiting, and pain in the body after injections. Discharged fairly fit and free from bladder symptoms Dec. 19th, 1918.

CASE 6.—Pte. M., aged 21. Admitted Sept. 21st, 1918. Sent direct from Egypt, where he had been since December, 1915. Hæmaturia commenced May, 1916. Urine showed a trace of albumin and abundance of red blood cells and terminal-spined bilharzia ova. 30½ gr. tartar emetic injected. Symptoms produced were immediate cough, giddiness, vomiting, slight diarrhoea, and stiffness in shoulder muscles. Blood and ova not found again. Discharged well Dec. 19th, 1918.

CASE 7.—L cpl. D., aged 22. Admitted Sept. 9th, 1918. Went to Egypt November, 1915. Hæmaturia first observed at Fayoum October, 1916. Urine contained terminal-spined bilharzia ova, red blood cells, and a trace of albumin. Sixteen injections (29 gr.) tartar emetic. No ova after completion of injections. Weight increased from 10 st. 7 lb. to 11 st. 4½ lb. Discharged well, except for a little weakness.

CASE 8.—Pte. G., aged 25. Admitted Jan. 17th, 1919. Sent direct from Egypt for bilharziasis. Was infected in the Fayoum District 1915-16. Blood cells and terminal-spined bilharzia ova abundant in urine. 31½ gr. tartar emetic injected. Pyrexia (100°) and general pruritus occurred after two injections. No further blood or ova. Discharged well.

CASE 9.—Cpl. M., aged 30. Admitted Oct. 12th, 1918. Sent direct from Egypt for bilharziasis. Blood and terminal-spined bilharzia ova found in urine. 30 gr. tartar emetic injected. Irritative cough and headache after injections. No more blood or ova in urine. Discharged free from bladder symptoms, though still has slight dull pain in small of back, and patient considers he is weaker and more easily tired than before injections.

CASE 10.—Pte. C., aged 25. Admitted Nov. 12th, 1918. Was perfectly fit until sent to Egypt in September, 1915. Was stationed in the Fayoum Province until November, 1916, when he was sent to Palestine, where the hæmaturia commenced. Bilharzia ova found in urine. 30½ gr. tartar emetic injected. At the end of the course of injections the urine was free from ova, blood, and albumin, but patient still complained of pains in the back and over the bladder. During the following week there was a recurrence of the hæmaturia, with headache and more pain on micturition. The urine contained red blood cells and granular epithelial cells, but no ova were found. Patient was transferred to the 4th London General Hospital.

### Results.

In all these cases the solutions used were made by dissolving the tartar emetic in freshly distilled sterile water, 1 gr. in 6 c.cm., and then sterilised by autoclaving for one hour. At first the injections were administered every two days, with a maximum dose of 2 gr., whilst on the later cases I worked up to doses of 3 gr. twice a week. No serious drawback, no marked toxic manifestations, and no severe reactions followed the injections. With one exception all

the patients were troubled with irritation of the pharynx and a spasmodic outburst of coughing either during or after the injections, usually just at the end of administration. In four cases stiffness and cramp of the muscles of the neck and shoulder girdle were complained of. Gastro-intestinal symptoms were fairly frequent, comprising nausea in 3 cases, vomiting (usually once only) in 4 cases, and slight diarrhoea in 3 cases. Headache was noted in 2 cases. There was induration at the seat of injection in 2 cases. Pyrexia (to 103° F.), slight giddiness, pains in the body, general pruritus, and loss of weight were noticed in 1 case each.

#### Untoward Effects of the Injections.

Cases.	Cases.
Cough and pharyngeal irritation ... .. 9	Induration ... .. 2
Stiffness of neck and shoulder muscles ... .. 4	Pyrexia (to 103° F.) ... .. 1
Nausea ... .. 3	Giddiness (slight) ... .. 1
Vomiting (slight) ... .. 4	Pains in the body ... .. 1
Diarrhoea (slight) ... .. 3	General pruritus ... .. 1
Headache ... .. 2	Loss of weight ... .. 1
	Relapse of hæmaturia ... .. 1

The immediate results were very striking and comprised a rapid disappearance of the blood and ova from the urine, disappearance or mitigation of the hypogastric and perineal pains and pain in micturition, improvement in anæmia, gain of weight, and a quite striking improvement in general appearance and feeling of well-being. The remote results I am unable to discuss owing to the short time elapsed and to the fact that all the patients have left the hospital. As far as is known all the cases have remained free from symptoms except Case 10, who developed a smart hæmaturia within a week of completing the course of injections; no ova could be discovered on microscopic examination of his urine.

Case 3 was so pleased that he writes from the country under date Dec. 22nd, 1918:—

"The hæmorrhage has completely stopped, and bar a little pain in the affected region I am practically fit" (although he states elsewhere his duties are not of a very light character). "There are one or two fellows here who are discharged with bilharzia and have had no treatment whatever. They are naturally anxious to undergo this particular treatment. I should be greatly obliged if you could inform me as to the course they should adopt to obtain it."

That tartar emetic injected intravenously exerts a strikingly beneficial effect on vesical bilharziasis is amply demonstrated by the cases here recorded, but how this effect is produced is not so evident. That the drug kills or inhibits the activity of the parasite appears the most reasonable suggestion. At what stage in the life history of the parasite this occurs, whether ovum, miracidium, or adult worm, or all three, has not yet been demonstrated. Christopherson claims that the tartar emetic exerts a direct helminthocidal action on the adult worm. Direct experimental proof on this point is still lacking, though Archibald and Innes's case, the only one so far submitted to post-mortem examination, provides some support for this view.

#### The Toxicity of Tartar Emetic.

The high toxicity of tartar emetic has always been a matter of serious concern to those employing it in intravenous injections, especially in the intensive manner now prevailing for the treatment of bilharziasis, trypanosomiasis, and leishmaniasis. That such injections are not free from risk is shown by Knowles<sup>6</sup> and by Archibald and Innes.<sup>7</sup> The former recorded 5 deaths out of 20 cases of kala-azar treated by tartar emetic, whilst the latter record a fatal case of bilharzia so treated.

The case of Archibald and Innes was a strong Egyptian soldier suffering from hæmaturia, whose urine showed a heavy infection with terminal-spined ova of bilharzia. The solution employed for intravenous injection contained 1 gr. of the drug dissolved in 2 c.cm. of sterile water, being mixed immediately before use with an equal amount of sterile normal saline solution. The initial dose was  $\frac{1}{2}$  gr., gradually increasing to a maximum of 2 gr., until a total of 33 gr. were given, the injections being given every second day. At the end of the treatment the urine contained blood, but no ova. The patient then developed influenza, and died on the fourth day of the illness from broncho-pneumonia. At the autopsy no adult worms could be found, though the congested mucous membrane of the bladder contained large numbers of bilharzial ova. The liver and kidney cells and the tunica intima of the inferior vena cava showed fatty degeneration and fatty

infiltration, changes which were attributed to the action of tartar emetic, and were not sequels of bilharzia, influenza, or a previous malarial infection.

This opinion of Archibald and Innes appears correct, as somewhat similar changes are found in the liver in certain toxic conditions, especially in the closely allied conditions of arsenic and phosphorus poisoning, and as was found by Gregorson and Taylor<sup>8</sup> in trinitrotoluol poisoning. The toxins attributed to the ova and miracidia of bilharzia by two Japanese observers, Kiyono and Murakami,<sup>9</sup> do not appear to produce fatty changes in the liver, but lead to a cirrhotic condition of that organ.

Although in Archibald and Innes's case the cause of death appears to have been influenzal broncho-pneumonia the degenerative changes in the liver and kidneys may have been recoverable, or may have been due to undue susceptibility of the patient to antimony. That very much larger doses of tartar emetic can be given intravenously with perfect safety is evident by a case under the care of Dr. C. W. Daniels, treated by Dr. H. B. Newham, C.M.G.,<sup>10</sup> at the Seamen's Branch Hospital attached to the London School of Tropical Medicine.

This was a patient infected with *Trypanosoma rhodesiense*, who received 236 bi-weekly intravenous injections of tartar emetic in the course of two and a half years. The maximum dose was 2½ gr., and the total quantity administered amounted to the enormous total of 550 gr. The patience of the physician and the fortitude of the patient were finally rewarded by the complete recovery of the patient from the most virulent of all the forms of trypanosomiasis, and the patient remains free from symptoms both of the disease and of antimony poisoning until the present day.

#### Less Toxic Compounds of Antimony.

Since the risks of antimony poisoning as the result of intravenous injections, though apparently not very great, cannot be ignored, other forms of antimony should be sought combining equal therapeutic effects with diminished toxicity. Antimony and arsenic are so closely allied in their chemical characters that this condition would probably be brought about by the production of organic compounds of antimony. Since antimony and arsenic are so closely allied in their chemical characters and the toxicity of arsenic has been greatly reduced without diminishing its therapeutic action by introducing arsenic in organic combinations in such drugs as salvarsan and its substitutes, it would appear highly probable that similar organic compounds of antimony could be produced and that the effects of the antimony would be similarly influenced.

In view of the prevalence of trypanosomiasis, leishmaniasis, and bilharziasis in various parts of the world and the undoubted beneficial action of antimony compounds on these diseases, the production or thorough investigation of such organic compounds of antimony is one of the pressing problems of the day in tropical medicine.

Meanwhile Sir Leonard Rogers<sup>11</sup> has drawn attention to the occasional danger from the toxicity of tartar emetic intravenously, and has done the pioneer work in searching for equally efficient but less toxic forms of antimony. In 1916 he recommended sodium antimony tartrate, Plimmer's salt. More recently he has employed colloid antimony sulphide intravenously in kala-azar. He found it effective in smaller doses, being retained in the blood longer than the soluble tartrates of antimony, and concludes that colloid antimony sulphide appears a distinct advance on soluble antimony tartrates. It is evident that colloid antimony sulphide given intravenously would be well worth trying in bilharziasis.

I am indebted to Lieutenant-Colonel Maretts Tims, R.A.M.C., Officer Commanding the Bermondsey Military Hospital, for permission to publish these cases, and to Captain F. Talbot, R.A.M.C., and Drs. R. H. Townend, J. Howard Cook, A. M. Cato, and A. E. Wilson, for permission to use the cases under their care.

# SUPPLEMENTARY NOTE ON JAUNDICE AMONG THE BRITISH TROOPS IN NORTHERN ITALY.

THE following is an addendum to the article under the above heading by Dr. H. H. TOOTH and Dr. E. G. PRINGLE which appeared in THE LANCET of July 26th, 1919 :—

## Addendum.

Lieut.-Colonel A. E. Gates, consulting physician at the forward area at the time when our cases were recorded, has kindly allowed us to include abstracts of notes of four cases, two of which were fatal but presented no evidence of spirochætosis. But the blood of the two that recovered grew spirochætes in guinea-pigs. The cases were briefly as follows :—

1. Pte. B. Onset sudden, Sept. 2nd, 1918, with headache and general illness. On the 6th, vomiting; 7th, admitted to hospital. Marked jaundice, conjunctivæ injected. 8th, impaired resonance and moist sounds in right lung posteriorly. 10th, copious pasty motions with much blood clot. 13th, died. Low grade of fever 99°–100°, rising to 102° on day of death. Sputum, no influenza bacilli, predominant organisms pneumococci. Post-mortem: Confluent bronchopneumonia lower lobe of right lung, discrete and hæmorrhagic of left. Gall-bladder distended with thick dark bile, common duct occluded by blood clot. Punctiform submucous hæmorrhages in stomach and intestines. Microscopic examination by Professor Bonome, of Padua: Left lung multiple foci of acute hæmorrhagic broncho-pneumonia, no Gram-staining micro-organisms or spirochætes. Liver, slight grade of acute atrophy, and slight small-celled infiltration of bile passages. Spleen congested, numerous small hæmorrhages in pulp.

2. Pte. N. D. Admitted August 28th, 1918, as a case of pneumonia. Jaundice developed on sixth day of illness, fæces clay-coloured, bile and albumin in urine. Temperature for first six days about 102°, fell to subnormal on appearance of jaundice, when pulse rose to 160, with delirium, epistaxis, and hæmatemesis, and purpuric eruption on the buttocks. Died on Sept. 1st. Guinea-pig inoculated with blood 12 hours before death with no result. Post-mortem: lungs congested, many small hæmorrhages. Liver, no abnormality. Gall-bladder contained a small quantity of bile. Common duct patent. Spleen enlarged. Kidney, capsule strips with difficulty, multiple punctiform hæmorrhages. Stomach and jejunum, small submucous hæmorrhages. Microscopic examination by Professor Bonome: Liver, slight grade of acute atrophy of hepatic cells, dilatation of intrahepatic bile canaliculi, with small-celled infiltration of the connective tissue; no Gram-staining micro-organisms, no spirochætes. Kidneys, acute nephritis, chiefly glomerular and interstitial. Spleen, small disseminated hæmorrhages.

3. Qm. S. C. Sudden onset Sept. 4th, 1918, with headache and general illness. Temperature 103°6', and raised until ninth day of disease. Jaundice and herpes labialis on the fourth day. Slight purpuric rash on sixth day. Photophobia. Urine contained bile, albumin, and casts. Blood culture negative, "but inoculated guinea-pig died with a few spirochætes."

4. Driver F. Admitted Sept. 16th, 1918. Onset sudden three days before, with headache and general illness. Jaundice on the third day. Temperature 103°, falling to subnormal on the seventh day for a period of eight days, after which a daily variation from 97° to 101° or 102° for 14 days or more, when he was transferred to the base. Urine examined for spirochætes on the eleventh and thirteenth days with negative results. A guinea-pig inoculated with the blood of the sixth day died, and spirochætes were found in its liver.

The two cases of ascertained spirochætosis seem to weaken the suggestion, in the concluding remarks of the article, that another infective virus was possible, but the question whether two positives are to be accepted as invalidating so many negatives must be left to the judgment of the reader.

## Medical Societies.

### MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND : THE ANNUAL MEETING.

THE seventy-eighth annual meeting was held at York on July 22nd and 23rd, under the presidency of Lieutenant-Colonel J. KEAY and, later, that of Dr. BEDFORD PIERCE.

#### Coördination in the Asylum Services.

Dr. J. G. SOUTAR moved the following resolution :—

"That a deputation be appointed to place before the Minister of Health the opinion of the Medico-Psychological Association that all matters concerning the care of the insane in England and Wales should as soon as possible be brought within the authority of the Ministry of Health; and that the Board of Control, whose sympathetic experience and encouragement in all matters concerning the welfare of the insane has been so valuable, be maintained for the department."

Dr. Soutar said they all recognised that coördination ought to exist in what they might call the asylum services generally. They felt it was preferable that the coördinating body should be within a Government department specially constituted to deal with the health of the whole community, rather than left to some self-appointed body which was inclined to consider asylum administration from a lay point of view and to eliminate the medical element. All who had had experience had seen for a long time that the Board of Control had maintained a most sympathetic attitude towards ideas of progress and advancement in matters of the insane. That was becoming more and more a medical, and less and less a legal, matter. The experience of the members of the Board of Control was vast; it would be a disaster if that sympathetic body should be scrapped and some new body established when the administration of lunacy passed into the hands of the Ministry of Health.

Dr. SHAW BOLTON said it was not fully realised how much it was desired by some members of asylum committees to eliminate the Board of Control. The object of the National Federation was to establish mental hospitals free from the Board of Control. He was strongly in favour of Dr. Soutar's resolution.

Dr. C. F. FOTHERGILL asked if it would include borderline conditions.

Dr. SOUTAR said they would rather not include them.

The resolution was carried unanimously, and it was agreed to send a copy of it to Dr. Addison, the Minister of Health, with a request that he would receive a deputation.

#### Training of Mental Nurses.

Dr. G. M. ROBERTSON said what was required in mental cases was two different qualifications. In the first place, the person must be a skilled nurse who knew how to care for sick people and look after the mentally deranged people. In the second place, it was important that he or she should be a person of good character upon whom they could rely. He ventured to say the character of a mental nurse was more important than the technical training. He moved :—

"That in future the three years' course of training for nurses applying for a certificate shall be taken in one mental hospital in place of not more than two hospitals."

Dr. W. F. MENZIES opposed the proposal. He thought that if the superintendent could not judge in six or nine months of the character of a nurse then he was not able to give any certificate of character at all.

Dr. SHAW BOLTON said that ever since he had been a superintendent he had systematically refused to take nurses from other institutions because they had so much to unlearn. He would like to see the question of training pressed to the fore.

The PRESIDENT put the motion, and Dr. Robertson's resolution was declared carried by a majority.

#### Hypnotic Suggestion.

Dr. G. R. JEFFREY read notes on a case treated by hypnotic suggestion. He referred to the great difficulty in the treatment of mental illnesses, and brought before the meeting notes

of a case which was treated by hypnosis and suggestion. He further suggested that even in advanced mental disease this method of treatment was, in suitable cases, always worthy of consideration. Dr. Jeffrey, in a few words, referred to the value of this method of treatment during the recent war in dealing with all sorts of so-called functional diseases of the nervous system. The case which formed the basis of this paper was that of a young woman who, after several months of very indifferent mental health, became distinctly worse after a dream, in which she dreamt that the sun and the moon had come into collision, with the result that the world was submerged in blood. She awoke from her dream in a state of terror, dazed and confused, and finally sought admission to Bootham Park Mental Hospital as a voluntary boarder. Under the influence of light hypnosis her illness was explained to her, and suggestion treatment generally was employed. She awoke next morning quite well, and left the hospital completely recovered after five days' residence.

Dr. ROBERTSON said he found in all cases in which he attempted hypnosis those suffering from melancholia were most difficult to deal with, whilst those with acute mania were extremely suggestible and easily hypnotised. Dr. Jeffrey had pointed out that the symptoms did not resemble those of ordinary melancholia; it was probably a case of what was known as anxiety neurosis. He (Dr. Robertson) thought that the dream which was related showed a decided sexual element.

Dr. R. M. LADELL agreed that melancholic patients were practically impossible to hypnotise. He wondered if it would be wise to drug patients sufficiently to get them quieter and then to superimpose hypnosis.

Dr. H. M. EUSTACE congratulated Dr. Jeffrey on being able to induce hypnosis. They realised personal magnetism was needed to induce it, and all had not the power.

Dr. JEFFREY agreed that it was a case of anxiety neurosis. He entirely disagreed with the sexual explanation. He gave particular care to try to find out if there was any sexual point, and there was none. He induced hypnosis in the usual way.

#### *A Representative from Paris.*

The PRESIDENT said that at this annual meeting they were honoured by the presence of a representative of the Medico-Psychological Society of Paris, Dr. Henri Colin, its honorary secretary. To our distinguished guest they extended a warm greeting and a hearty welcome, not only on account of his eminence as an alienist, and of the fact that he represents the sister society at our meeting, to which we are united by bonds of growing esteem and affection, but, if possible, even more so because he stands for closer union in all things with our brave and glorious ally, the heroic and immortal France.

#### *Members Entertained.*

Members were entertained to luncheon at the Retreat, Mr. YEOMANS, chairman of the Committee of Management, presiding.

The PRESIDENT, in thanking the committee for their hospitality, explained that the Association was practically an Irish association, and between Irishmen and Yorkshiremen were many points of similarity. They therefore expected to receive the kind of hospitality they had, and they showed it by coming to the Retreat for their new President. They had admired the committee's splendid hospital with its historic associations and its world-wide reputation for all that was good.

The CHAIRMAN said the committee appreciated the kind words which had been said. It was not the first time the Association had visited York. He remembered that his predecessor, the then chairman, took the opportunity of urging improvements in the education and status of nurses and encouraging a higher type of woman to engage in the nursing of the insane. He believed that idea had permeated the asylum world, and though they still had a nursing question it was of a very different character. They had endeavoured to preserve the homely character and domesticity of the institution, which had always been a feature of the Retreat. It was founded by William Tuke in 1796 and was the first asylum in England established on humane lines. Members subsequently inspected the buildings, and viewed with great interest the archives and other historic treasures of the committee.

#### *The Afternoon Session.*

At the afternoon session Dr. PERCY SMITH proposed a vote of thanks to the retiring President and officers of the

Association. Colonel Keay had occupied the presidential chair for a year in addition to carrying on military duties, and they offered their hearty thanks to him. Dr. Smith added that it was a pleasure to him that Colonel Keay was to be succeeded by one of his (Dr. Smith's) old assistants at Bethlem Hospital in 1891, he meant Dr. Bedford Pierce. He went on to say that but for the work of the permanent officers the Association could not go on every year. He thought special thanks were due to Dr. R. H. Stoen, the secretary (recently succeeded by Major R. Worth); to Dr. J. Chambers, the treasurer; the editors of the journal, who had had a very difficult and arduous task during the war; and the registrar. Also to the secretaries of the various divisions, who had accomplished most useful work.

Dr. C. C. EASTERBROOK seconded the motion, which was unanimously agreed to.

The PRESIDENT returned thanks on behalf of his colleagues and himself. He had great pleasure in handing over to Dr. Bedford Pierce the direction of affairs and ornamenting him with the badge of office.

Dr. PIERCE said he was very proud to wear the blue riband of the Association. He did not know that there was anything more pleasing in this world than to win the goodwill and appreciation of one's friends and colleagues. He had always been an ardent believer in the Association, and it would be a pleasure to him to do what he could to pilot it this next year.

The PRESIDENT announced that the Gaskell prize and gold medal had been awarded to Dr. James Walker and the bronze medal to Dr. R. Eiger. There had been no divisional prizes. He believed the papers sent in had been of exceptional excellence.

#### *Presidential Address.*

The PRESIDENT then delivered his address on "Psychiatry—a Hundred Years Ago," an abstract of which appeared in THE LANCET of August 2nd. Before doing so he referred to the death of one of the late presidents, Dr. Joseph Wigglesworth, a distinguished and able man. In 1883, while superintendent at Rainhill, where he spent nearly all his professional life, Dr. Wigglesworth won the prize for an essay in which he dealt with certain states of melancholia attonita, or acute dementia, showing the inflammatory changes in motor cells.

Dr. D. G. THOMSON, in moving a vote of thanks, said he looked back historically to the problems of years ago. He brought out the fact that we were asked to-day much the same problems as those of 3000 years ago. He, with Dr. Pierce, was hopeful of the ultimate solution of many of them, and we should not sink into the feeling that the questions of insanity were unknown and unknowable.

Dr. SOUTAR, in seconding, said that the illnesses with which we had to deal were often due to social conditions over which we must exercise control if we were to stem the tide of mental disease. The next step was to deal with incipient cases.

In the afternoon, the committee of the Retreat gave a garden party to the members and their friends, a large number of guests attending.

#### *Morning Session, July 23rd.*

At this session, with Dr. BEDFORD PIERCE, the President, in the chair, Dr. G. L. BRUNTON read his

#### *Notes on the Cytology of the Cerebro-spinal Fluid,*

based on the examination of 100 cases of mental disease by Alzheimer's method. This method has the great advantage that cells in a fluid can be treated and stained similar to the methods employed in the histo-pathology of the tissues. He concluded that the cells of the greatest diagnostic importance are the plasma cell, the phagocytic endothelial cell, and the lymphocyte in excess; and that a high cell-count with an excess of lymphocytes, together with the plasma cells, is strong evidence of a parasymphilitic lesion. A number of excellent coloured diagrams were exhibited to illustrate the paper.

An interesting discussion followed, in which Dr. G. M. ROBERTSON, Captain OLIVER LATHAM (Australia), and Dr. F. H. EDWARDS took part.

Captain LATHAM said it was the custom in New South Wales to examine cases (of general paralysis) by Wassermann reaction; if no result, the cerebro-spinal fluid was examined by the method used for counting white blood corpuscles. They found this worked very well. Captain

Latham described at length cases of insanity frequent among children in Brisbane due to lead poisoning caused by scraping powder-paint from the verandahs.

The PRESIDENT contrasted the coördination in pathological work between asylums in N.S. Wales and those in this country, where every institution had to do what it could by itself.

Dr. J. E. MIDDLEMISS read a paper on

*An Analysis of 200 Cases of Mental Defect.*

The cases dealt with were analysed in tabular form from various aspects. The number of cases comprised under the four types recognised under the Mental Deficiency Act (1913) was given, as well as the number coming under the recognised clinical groups. The cases were further tabulated from the point of view of the different aetiological or associated factors. Reasons were adduced for regarding the customary division into primary and secondary groups as unsatisfactory. It was pointed out that on investigation cases of ementia presented every degree and variety of combination of the primary and secondary factors, so that it was frequently impossible to classify them on these lines. Instead, a broad division into two main types was advocated according to the presence or absence of a decided neuropathic strain as shown in the family history. Attention was drawn to two varieties of stigmata of degeneration not usually emphasised in the literature. 1. Variations in the actual as well as the relative lengths of the digits of both upper and lower extremities, but particularly the former. 2. Variations in the superficial reflexes. These were shown to be frequently modified in the direction of hyper- or hypo-acuity, there being no constant relationship in the degree of response in the reflexes examined in each individual case.

Colonel W. R. DAWSON and Dr. EDWARDS contributed to the discussion on this paper.

Dr. HENRI COLIN (Paris) contributed a paper on

*The Influence of War Fatigue on General Paralysis.*

Dr. Colin said that the influence of the war was much greater than at first supposed. He drew attention to the fact that the emotions, the result of the war, were a very strong causative factor in general paralysis. He also drew attention to the very great acceleration of symptoms and the rapidity with which general paralysis developed following the shocks and general emotional state of those who had served in the trenches. In the case of many prisoners of war who had developed syphilis it was only a few months after the infection that symptoms of general paralysis supervened and death followed within a few months.

The PRESIDENT said the paper raised many questions of serious importance. Service members could speak to the acceleration of general paralysis due to war conditions. The whole question (of general paralysis) was in a very unsatisfactory position. He was much struck by the facts Dr. Colin brought out as to the effect of emotion, accident, &c., on the course of general paralysis.

Colonel DAWSON wished to know if alcoholism played a leading part in Dr. Colin's case.

Dr. ROBERTSON confirmed the rapid course of general paralysis during the war from observations at Morningside. He agreed with the statement, "No syphilis, no general paralysis," as true.

Dr. M. ROSS related his experiences in a military hospital during the latter part of the war. There were a large number of young men there, many with recent syphilis. Of these a large number died within a short time or became moribund. Dr. Ross said that a lot of the repatriated prisoners had turned out to have general paralysis. These men had been exposed to all sorts of privation, and most had a history of brutality as well.

Captain LATHAM described the treatment of general paralysis with salvarsanised serum in temporary hospitals in Australia. He said general paralysis was very serious in Sydney and one of the most important causes of death in New South Wales.

Dr. COLIN, replying, said they were agreed that alcohol, besides syphilis, must be a factor of general paralysis. He agreed with Dr. Robertson that syphilis was the primary factor, but, though the primary cause, there were many other contributory ones. There was a general lack of recognition of paralysis both here and in France, where many paralytics had been swept into the army. The knowledge of mental diseases was backward in every country.

## Reviews and Notices of Books.

*Geriatrics: the Diseases of Old Age and their Treatment, including Physiological Old Age, Home and Institutional Care, and Medico-Legal Relations.* By I. L. NASCHER, M.D., Chief of Clinic Department of Internal Medicine, Mount Sinai Hospital Dispensary, New York, &c. With an Introduction by A. JACOBI, M.D. Second edition, revised. 50 plates, containing 81 illustrations. London: Kegan Paul, Trench, Trübner, and Co. 1919. Pp. xx. + 527. 21s.

THIS book is not a treatise on how to prolong life, but rather a text-book of diseases and morbid conditions—as they present themselves to medical practitioners in their treatment of aged patients—giving rise to what the author terms *pathological* old age. Old age in itself is not pathological, and normal old age, to which the author devotes a first portion of the book, cannot be remedied. He discusses the anatomical and functional changes connected with the physiological state of senility, and shortly reviews the theories of the causation of ageing. But the bulk of the book is given up to a methodical account of the diseases and morbid conditions of old age, in which senile diseases are considered as (1) primary, (2) secondary, (3) preferential, and (4) modified, the latter dealing with such diseases as asthma and pneumonia when complicated by senility.

Following all this a considerable portion of the book is given up to the long series of diseases which are relatively uninfluenced by old age, such as many acute infectious diseases, leukaemia, muscular rheumatism, &c. The 11 pages on Surgical Procedure in Senile Cases—a fresh chapter introduced into the second edition—are based "upon the views and experiences of surgeons who have had an extensive practice in senile cases." The author says that, in spite of a few optimistic sentiments that have been expressed on the subject, surgeons generally never operate upon a senile case if operation is avoidable. He holds that the saying, "Age is no bar to surgical operations," should be accepted "only if the infirmities and debilities, the degenerations and pathological conditions to which the aged are particularly liable, are kept in mind at every stage through the pre-operative period to complete convalescence."

Very important is the final section of the book on the Hygiene of the Aged (Home Care and Institutional Care) and the Medico-Legal Relations of Old Age, including such subjects as Sir George H. Savage recently and ably dealt with in his post-graduate lecture on "Mental Disorders Associated with Old Age." We do not believe that it is human nature in most parts of the world to give less attention to the wants of the aged members than of the infantile members of the family (and in this respect the *dutiful* sons and daughters of Hebrew families in the East End of London may especially be referred to). The reverse seems rather to be the case, and the fact that the present large work has already reached the stage of a second edition seems to support our view. We feel tempted to prophecy that there will be a growing demand for this kind of book.

In regard to treatment, as already stated, the author does not seek to remove the normal infirmities of old age—what he wishes to help in is to convert a *pathological old age* into a *physiological* one. The subject is a very complicated one on which much remains to be studied and discussed. On p. 17 the author writes: "The popular conception of old age is based upon the appearance of the individual. It is not unusual, however, to find apparently decrepit individuals regain strength, mental activity, cheerfulness and a more buoyant spirit, as well as a more youthful appearance when freed from care and the necessity to work. This is a common observation in inmates of homes for the aged shortly after their admission." But is not this partly due to a kind of reawakening of the mind by the altered, and doubtless improved, social surroundings? Freedom from care and from work may have a quite different effect, according to what is observed in the upper and middle classes, when a man retires from his profession or business, and is without sufficient interests, including "hobbies," to keep his mind

exercised *as well as his body*. Exercise for the body and occupation of some kind for the mind are as necessary in old age as at any other period of life—if not more so! Without them the body soon loses in vigour and in resistance towards disease, whilst the mind more rapidly degenerates and more readily falls a victim to morbid “growths,” which arise like tares in neglected soil—“mental growths,” which not only prey upon the mental faculties, but indirectly involve and play havoc with the functions of other organs besides the brain.

*On Longevity and Means for the Prolongation of Life.* By Sir HERMANN WEBER, M.D., F.R.C.P. London: Macmillan and Co., Ltd. Fifth edition. 1919. Pp. 292. 12s.

NOT many authors have so soundly justified the principles which they laid down for the pursuit of a certain course as did Sir Hermann Weber in this treatise on the prolongation of life, for he died in his ninety-fifth year. The edition now before us, the fifth, was in type at the time of his death, and is issued under the editorship of his son, Dr. F. Parkes Weber. The book is an expansion of a lecture delivered before the Royal College of Physicians of London in 1903, when the author had already attained the respectable age of 80 years. The book is full of sound sense, and is founded upon a belief in exercise, fresh air, moderation, cleanliness, and cheerfulness. This is a following of the old Salernitan dictum:—

Si tibi deficient medici, medici tibi fiant,  
Hæc tria, mens hilaris, requies moderata, diæta.

We are glad to see that Sir Hermann Weber speaks in praise of gardening, for it is an admirable and useful occupation for those getting on in years, though we rather demur to his description of weeding as a “light” occupation. Gardening certainly conduces to sound wholesome sleep at night and is a means for keeping a man out in the air, especially those—and they are many—to whom walking is anathema. Sir Hermann Weber’s remarks upon diet are in general thoroughly commendable, but we think that he is a little too sweeping in his condemnation of wine. Many elderly persons find that, say, a pint of really sound light claret in the 24 hours has no harmful effect, but rather the contrary, in that it aids digestion. At the time of the death of Sir Moses Montefiore, who died in his hundredth year, it was currently reported that he had drunk a bottle of port every day of his life since he grew up. His is not an example to be followed, for the ordinary man is better without alcohol except in a really moderate amount and in the shape of a wine of good quality.

*The Diagnosis and Treatment of Heart Disease.* By E. M. BROCKBANK, M.D. Vict., F.R.C.P. Fourth edition. With illustrations. London: H. K. Lewis and Co., Ltd. 1919. Pp. 158. 5s.

IN its rapid passage through three editions this little collection of practical points for students and practitioners has not had an opportunity to get out of date. Several alterations and some additions have, however, been made to the third edition, and the text is practical and reliable as ever. Students who think that they know all about the auscultation of the heart will do well to read it through before their final examination.

*Instrumental Orthopædics (De l'Orthopédie Instrumentale).* By Dr. GABRIEL BIDOU. May, 1919. Twenty plates. Imprimerie des Orphelins-Apprentis d'Auteuil, 40, rue La Fontaine, Paris. Pp. 132.

THIS little book, which deals chiefly with the instrumental treatment of paraplegia, discusses at some length the principles on which apparatus should be constructed. The author advocates celluloid in place of leather, and has adopted the principle of active control which is so well known in the American type of artificial leg. He also employs indiarubber springs, and in certain cases multiplies the range of movement by the use of pulleys and levers.

*The Great War Brings it Home.* By JOHN HARGRAVE. London: Constable and Co. 1919. Pp. 367. 10s. 6d.

THE argument of this book is an essay in sociology. The present state of civilisation is considered to result from an unhealthy, because restricted, development of the individual. We are living by purpose instead of by impulse, and so are

losing in vitality and suffering from the effects of repressed instinct. The Great War has awakened us to the fact that we are moving along a false trail. The right way is the natural way: the normal instincts if allowed freedom to develop from an early age will produce, according to the author’s view, a higher type of creature. The argument is profusely illustrated from a wide knowledge of primitive life and customs. The careful reader will find many criticisms to make, and though he may not be convinced by the argument he cannot fail to be interested by the illustrative detail.

*Induction Coils in Theory and Practice.* By Professor F. E. AUSTEN, E.E., U.S.A. London: Messrs. E. and F. N. Spon, Ltd. 1919. Pp. 64. 5s. net.

IT is difficult to conceive of any class of student to whom this book could be recommended. It is of the “potted” order, being divided into 245 numbered paragraphs, ranging from a definition of the term “equation” to an explanation of the exponential function. There are occasional excursions into the Calculus, and the amount of logic in the arrangement may be estimated from the fact that para. 110 contains a differential equation, and para. 235 deals with the theorem of Pythagoras. The subject-matter is the result, so we are told in the preface, of the author’s experience in directing courses in the American Army. We must suppose that the luckless students had to face these 245 paragraphs much as they might have to face the Chinese characters. No explanation is given of the almost uni-directional character of the secondary discharge or of the effect of the condenser. There are two graphs in the book, on one of which the coordinate units are not even indicated.

Some of the diagrammatic representations of apparatus are good, and the specifications of different types of coil are of value to those who wish to build up coils of their own, though the same information could probably be obtained from a shilling manual.

## JOURNALS.

*Mental Hygiene.* Vol. III. No. 1. January, 1919.—This number contains several articles by some of the leading psychiatrists of America, who have succeeded in writing in an entirely popular style in order that the journal may appeal to the lay mind. While this is a feat of no small merit in itself it does inevitably result in certain limitations. There is, for instance, a tendency to multiply words and examples as well as a striking absence of references. The organisation of the neurological department of the American medical service in the late war is the subject of an editorial article. Profiting by the experience gained during the earlier part of the war in the French and British Armies, the Americans attached to each division a neuropsychiatrist, who was stationed in the most advanced field hospital. This arrangement proved the value of early treatment in war neuroses. Only 1 per cent. of the cases presenting themselves at the advanced hospital were ultimately invalided to America.—Dr. Macfie Campbell has contributed an interesting paper on Nervous Children and their Training. He attributes to errors in home education at an early age many of those untoward and “irregular” symptoms which cause so much trouble in later life. A number of cases are quoted to illustrate the harmful results of indulging the caprices of sensitive children instead of helping them to adapt themselves to their environment. The physician in these cases has to treat the nervous child by educating the parents. He has, in short, to treat not a symptom but a situation.—Dr. Adolph Meyer discusses the Right to Marry. Excluding “imbeciles and many psychopaths,” and granting the possibility of a healthy environment for the future children, he believes that an individual of “tainted stock” should be allowed to marry another whose ancestry shows only normal individuals. Marriages cannot be controlled by law, nor are intentionally childless marriages to be encouraged. A propaganda of the laws of heredity, so that marriage shall not be undertaken without a clear understanding on the part of both contracting parties, is advocated as the better way. Runaway marriages should be made a legal impossibility, as they are in Switzerland.—The annual census of the insane is considered statistically by H. M. Pollock, Ph.D., and E. M. Furbush, A.B., B.S.—There are articles also of interest to the sociologist and educationalist, as well as abstracts of reviews of English and American literature.

In the *Military Surgeon* (Washington, D.C., U.S.A.) for May Professor Theodore Tuffier, consulting surgeon to the French Army, gives an account of the transport service for

wounded by aeroplane as it was extemporised in the Sahara with its wide spaces, turbulent tribes, and military posts, hardly accessible except by air. A general officer, wounded in the chest at Tafilalet in South Morocco, had to be carried 26 miles by bearers to Ksar-es-Souk. A major of the French Medical Service was sent to him by aeroplane, 200 miles over the mountains and into the desert. The patient was found to require an X ray examination, which would only be given at Bou-Denib, 60 miles away and isolated by enemy forces. There was nothing for it but to transport the patient thither by aeroplane, which was done in an hour by a Farman aeroplane, and the subsequent operation was now carried out with knowledge, and, happily, with success. Professor Tuffier goes on to say that an aero-ambulance service is in organised existence in the South of Algeria (Sahara) and in Tunis. Patients are carried about 100 miles a day, generally in Farman aeroplanes, and they should be sent in the early morning. It is, however, impossible to send them during a Scirocco wind, which shrouds the desert in a high, dense dust-cloud and prevents the pilot from finding his way and makes landing impossible.—Major M. C. Winternitz, U.S.M.C., details the damage done to the lungs of dogs by irritating poison shell gases, and shows that the ultimate effects closely resemble those of influenzal pneumonia, the pathology being similar. In each the epithelium of the air-passages is destroyed, the lung thus loses its protection and is exposed to infection from the bacilli of the mouth, which rapidly spread through the extensively oedematous pulmonary tissue. It will be recalled that in the April number of this magazine Major Dodge mentioned that a 1 in 10,000 quinine sulphate gargle seemed to protect influenza cases from pneumonia.<sup>1</sup> Mustard gas sets up a spasm of the bronchioles which keeps it out of the air vesicles, but where it does reach the lung it causes necrosis. (The worst examples of necrosis of epithelium in larynx and bronchi in the College of Surgeons War Museum are ascribed to mustard gas.) Chlorine and phosgene have similar actions, but chlorine acts more on the upper air passages, phosgene on the vesicles, in which it breaks up, forming nascent chlorine. The paper, which is the outcome of experiments on some 1500 subjects, should be read.—Lieutenant-Colonel W. B. Cannon tells of his researches on wound shock, which is, he urges, a toxæmia due to absorption of poisons from dead or dying cells. These poisons cause great outflow from the blood-vessels into lymph spaces with resultant halving of the blood pressure. Thus he accounts for the sweating and chilliness of the patient and the poor circulation with accumulation of red blood cells in the peripheral vessels, consequently poor aeration of the tissues, and in the advanced stages air hunger. He recommends, as the first treatment, warmth. If the patient is on a stretcher he should have blankets below him as well as above; rectal or intravenous saline injections or gum-salt solution injections should ring the changes with transfusion. Tourniquets are not to be lightly removed from shattered limbs; they prevent the shock-toxins becoming diffused through the body, and shock has often appeared for the first time just after a tourniquet has been removed. The only anæsthetic to be used in shock is nitrous oxide and oxygen. Thus he upholds the conclusion of Mr. Cowell in his Arris and Gale lecture.—Major J. Bayard Clark reports on what he saw of the treatment of venereal disease in England in 1918. He paid many surprise visits to military hospitals, which he always found clean and well managed, well equipped, and with a sufficient staff. He professes himself satisfied with us and notes that "the percentage of complications in all hospitals was very small."

#### THE ENHAM VILLAGE CENTRE FOR THE RE-EDUCATION OF MEN DISABLED IN THE WAR.

THE first annual meeting of the Village Centres Council was held recently at the house of the chairman, Lord Henry Cavendish Bentinck, M.P., Sir George Makins, Vice-President, in the chair, when the administrator, Major Garthwaite, reported that the Enham Village Centre, opened for ex-Service men on May 31st, had 30 men in residence receiving medical treatment and undergoing training, mainly in horticulture, agriculture, and forestry. Workshops for basket-making, electrical fitting, and carpentry had also been opened, and in other directions the re-education of men disabled in the war was being undertaken.

Dr. Fortescue Fox, the medical director, said that the interval between a man's discharge from the army and his reception at Enham varied from 1 to 43 months, with an average period of 12 months in their own homes. Nineteen out of the total of 30 had not done any work during this time, and ten had attempted to return to work and

had broken down. All of them were now doing some work at Enham, under medical supervision, from two to six hours daily. Many kinds of physical and mental disability were represented. Nearly half the cases were definitely neurological, and under the care of Captain Douglas-Morris, R.A.M.C., the neurologist, who often made use of mental treatment with advantage. Several men had come with paresis, after fracture of the skull, and all of these were quite unfitted for the nervous strain and noise of town life, and had improved in the country. Cases of old wounds of the arm, with stiffness and wasting, were put to light curative work, such as thinning grapes, clipping hedges, sawing, or wood-cutting. Sensation as well as movement could be re-educated by appropriate work, such as planting seedlings or picking fruit. Games like bowls were very helpful. Whatever label was attached to the disability all the men should be regarded as neurasthenic. A large proportion—perhaps the greater number—would never be able to compete with able-bodied men in industry; therefore, looking ahead, it seemed likely that the Village Centre would become not only a centre for treatment and training, but a centre for providing special industries for permanently subnormal men, for whom there would always be needed a measure of protection. The process of re-education and the choice of their occupations required far more care than had hitherto been bestowed upon them, and should be based upon exact measurement of each man's physical and mental capabilities, with special regard to individual tastes as well as pre-war occupation, family circumstances, and the condition of the labour market. It was not sufficiently realised that the industry of the disabled, if properly guided, was capable of making a very large addition to the production of the country.

Mr. Rowntree, architect to the council, gave particulars of the housing scheme of the council. The Chairman and Sir R. Godlee expressed the hope that types of disablement would be selected for Enham which were capable of being effectually treated, so that a considerable number of cases could be passed rapidly through the centre.

## New Inventions.

### IMPROVED FORCEPS.

FOR the last four years all my artery and tissue forceps have been made with a bowed lock at the end as part of the circular finger ring. The illustration shows this lock applied to towel clips, to the Mayo-Ochsner angular forceps (open), and to mosquito forceps (closed). The advantages

of the attachment are greater resiliency and increased leverage in locking, more facile opening and closing, and—one great convenience—sutures are no longer liable to become caught up between the finger rings as with the ordinary forcep lock.

Messrs. Charles F. Thackray, Great George-street, Leeds, are the manufacturers.

LONDON: SATURDAY, AUGUST 9, 1919.

## An Anthropometric Index of Physical Fitness.

THAT little children are more apt than adults to suffer ill-effects from remaining uncovered in a cool atmosphere is a fact that is known to every mother, and all surgeons recognise the importance of keeping children warm when prolonged exposure on the operating table is necessary. The reason for this is that the surface area of the child's body bears a higher proportion to the body volume than is present in the larger body of the adult, since increase of volume outruns increase of surface with general growth of the body. We may say that body surface represents the area of heat loss, while, in great part, body volume represents the area of heat production. Considered in this simple way we would naturally be prepared to find that the expression of internal heat production should be "a simple function of the body surface," as in another column of THE LANCET Professor GEORGES DREYER has shown it to be, rather than "a simple function of height, as HUTCHINSON claimed." But Professor DREYER's important researches have proved much more than this. They not only show that the smaller and lighter individual, with his relatively larger surface, has a greater vital capacity per unit of body weight than the larger individual, but they also seem to prove quite definitely that no anthropometrical standard of health that has so far been suggested is so true an index of fitness as is the vital capacity when this factor is considered in its proper relations. Mere measurements of height, weight, girth, or proportions become insignificant as clues to physical fitness when they are compared with the vital capacity constant of Professor DREYER.

Professor DREYER's reference to HUTCHINSON recalls, and rightly, to the memory of medical men one whose painstaking and somewhat neglected work, given to the world over 70 years ago, seems now to be coming to its full appreciation. If the most recent research has shown that he was but a poor mathematician it has increased our admiration of him as a true pioneer possessed of accurate scientific insight. On April 28th, 1846, before the Royal Medical and Chirurgical Society, JOHN HUTCHINSON read a paper with the following title, "On the Capacity of the Lungs and on the Respiratory Movements, with the view of establishing a precise and easy method of detecting the disease by the spirometer."<sup>1</sup> In this paper, after describing the movements of respiration, he divided air into (1) residual air; (2) reserve air; (3) breathing air; (4) complementary air; and (5) vital capacity. His definitions seem to have been original in many ways, but were at once accepted, and for that matter most of his communication was perfectly sound. He narrated results which he had found in 2000 cases and showed the effects upon what he termed "vital capacity"—namely, "the greatest voluntary expiration following the deepest inspiration," which were produced by height, weight, age, and sickness. At

the same time he exhibited an instrument which he called a spirometer, and which was devised to record the respiratory movements in health and disease. Mr. HUTCHINSON's audience were obviously impressed by the industry and ingenuity which he had displayed throughout laborious investigations, and they appear to have accepted as a reasonable discovery his dictum that if the height of the individual be known, the number of cubic inches of air which he is able to expire in the healthy state can be calculated with tolerable accuracy. As Professor DREYER shows, this was an unwarranted deduction, but the value of the early researches remains.

The fixing of standards of vital capacity for the different elements of the population is a work of national importance, for by this means better than by any other shall we arrive at a true index of fitness from which the individual may be judged. Those upon whom the responsibility for the national health and national welfare will devolve should note the interesting fact that the Boy Scout possesses a vital capacity about 15 per cent. greater than the boy who is not a scout. Croakers about racial degeneration would do well to compare the vital capacities of the gentleman of to-day and of JOHN HUTCHINSON's gentleman of the "forties." But the most important result which we expect from Professor DREYER's work is a definite understanding, first among medical men, and secondly among the public, as to what significance is to be attached to the phrase "good physique." What does "good physique" mean? Vaguely we all know the kind of well-set-up individual implied, but when we go to see Mr. JAMES WILDE fight do we use this phrase about him? We do not, but clearly his physical fitness is colossal, though his frame is small. It is absolutely necessary that we should not be misled in the future by vague terminology, but should arrive at standards whereby physical fitness can be determined. The Medical Research Committee, whose assistance to Professor DREYER in his researches has been openhanded, is engaged at the moment in obtaining facts along similar lines, with the assistance of the heads of certain Government Departments. The results of these researches, when added to Professor DREYER's results, will supply a really important body of evidence upon which it should become easier to evaluate the normal criterions of health; we trust therefore that there may be no long tarrying.

## The Tuberculosis Curve.

THE ominous reports on the increasing prevalence of tuberculosis in many European countries have inevitably provoked criticism of anti-tuberculosis measures which a few years ago were almost tacitly accepted as sound and satisfactory. It was hoped of the Insurance Act, for example, that, framed as it was in many respects with special reference to tuberculosis, it would soon justify its existence by an appreciable fall in the death-rate from this disease. This hope has not been realised. But is this failure traceable to factors which the Insurance Act cannot, in common fairness, be expected to control, or is the Act directly to blame for the present state of affairs? Dr. B. G. M. BASKETT, of Rayleigh, appears, in an interesting communication he has addressed to us, to take the latter view. The economic factor is, in his opinion, the only one which explains all the phenomena of the

<sup>1</sup> THE LANCET, vol. i., 1846, p. 630.

tuberculosis death-rate in this country; and he sees in the Insurance Act, or rather in the policy of which the Act is the supreme expression, the cause of the conversion of a falling to a rising tuberculosis curve. His words are so much to the point that we reproduce them exactly:—

“Briefly, from 1840-1915 we have (1) a period of *laissez-faire*, with no public arrangements for treatment of disease and medical skill at its lowest—sequel, a huge drop; (2) a period of tempered *laissez-faire*—sequel, a slightly lower but very satisfactory continuation of the fall; (3) a period of municipal and State benevolence ever growing more intense—sequel (a) a slackened drop, and (b) an actual rise, after the largest measure of paternalism in English history. How are we to explain the brilliant success of *laissez-faire*, with medical knowledge at its lowest and no public means of treatment, and the dismal failure of State collectivism with indefinitely increased medical knowledge, and ‘all the means and appliances to boot’? Why should we have maintained almost constantly for 56 years a decrease of about 200 per million in the mortality in each five years, and have made less progress in the last 20 years than in any previous five, except two very early in the period? Why should we have been able justifiably to talk in the nineties of the approaching extinction of tuberculosis, when in 1918 the Registrar’s officer of statistics gravely suggests that it may be possible to revert to old conditions? I submit that there is only one factor which explains all the phenomena, the economic.”

No doubt the economic factor plays a very important part in tuberculosis. It is, in innumerable cases, the disease to which the poor man succumbs, and from which the rich man recovers. A balance at the bank, with balance of mind, is the best preventive of tuberculosis yet discovered. And the economic policy which secures the greatest prosperity for the working classes must, other things being equal, be the policy calculated to lower the tuberculosis rate most effectively. So far we agree with Dr. BASKETT, though we are not prepared at this juncture to discuss the respective merits of a *laissez-faire* or a paternal policy. Nor do we believe that sufficient data are yet available for forming a correct estimate of the effect, good or bad, of the Insurance Acts on the incidence of tuberculosis. The war alone has obscured the issues far too effectively for such a balance of accounts to be attempted at present. In regard to the influence of the war itself on the development of tuberculosis we think that some confusion has arisen from a failure to analyse carefully the factors concerned. It is evident that the fighting man in general, while exposed to horror and hardship, was obliged to live an active out-of-door existence, with the opportunity of an abundant diet and under the close supervision of a trained sanitary personnel. Even in countries where famine threatened every nerve was strained to keep up the physique of the men at the front. Undoubtedly these men have broken down with active tuberculosis in considerable numbers, but military service has not necessarily been attended with catastrophe in ex-sanatorium patients. How many compositors, shop-assistants, and brewers’ draymen, on the other hand, were prevented from becoming frankly tuberculous by their change of environment cannot, of course, be stated. But the number is large, even as numbers go in war-time.

A group of totally different factors was concerned in bringing about increased tuberculosis in civilian circles during the war. Here all the normal predisposing factors were present and accentuated, and on them were superimposed the limitation in diet—to put it mildly—and the hindrance to free

ventilation entailed by the light-screening regulations. It is therefore demonstrably absurd to suggest that the economic factor explains all the phenomena of the tuberculosis curve in this country. This curve is criticised because its steep decline is not maintained; it flattens out and then begins to rise. Setting aside this rise, which is largely, if not wholly, due to the war, even if influenced, as Dr. F. A. ELKINS and Dr. H. H. THOMSON show in an article appearing in our columns, by such a factor as overcrowding in asylums, we get a curve such as is obtained by emptying a viscid fluid out of a vessel where the emptying becomes progressively slower. Can the stamping out of a disease, the germs of which exist in over 90 per cent. of the adult inhabitants of civilised communities, follow any but a “viscid” curve? Leprosy was, no doubt, quickly stamped out in Norway by effective isolation measures, but, in spite of the close morphological relations of the two bacilli, leprosy and tuberculosis differ so fundamentally that this comparison is apt to be misleading. Isolation of the advanced consumptive—the prevention of massive infection—may be beneficial to the rest of the community, and it was suggested by KOCH that the abrupt fall in the tuberculosis death-rate in England in the middle of last century was to be traced to the segregation of dying consumptives under the Poor-law. But this same abrupt fall has also been correlated with the conversion of this country to an industrial life, which, it is argued, affords many opportunities for frequent accidental inoculation of small quantities of the tubercle bacillus—a beneficial process. Again, in the “sixties,” far-reaching sanitary reforms in certain English towns coincided with a remarkable drop in the tuberculosis death-rate; in Newport and Leicester it fell 32 per cent., in Salisbury 49 per cent. If we are to be perfectly candid, we must confess to considerable ignorance of the factors influencing the form of the tuberculosis curve during recent years. Dr. BASKETT’S questions, which pursue a frequent line of criticism, will be valuable if they stimulate research into the general conditions.

### The Holding of Inquests in Camera.

AT two recent inquests held by Dr. F. J. WALDO the cases have been of alleged suicide by the deceased throwing themselves in front of trains, and the coincidence led the coroner to offer suggestions as to the publicity now given to the proceedings at inquests. The juries endorsed his words, disclosing thereby what appears to be public opinion. Dr. WALDO’S view, which was to some extent supported by witnesses whom he questioned during the two sets of proceedings, is that the publication of the details of an inquest upon an apparent suicide has not infrequently put the idea of self-destruction into the minds of others. These persons may possibly be weak of intellect, or broken down by distress, or racked with apprehension; but though, for this reason or that, inclined to take their lives, the fatal determination dates from the moment when they read that fellow creatures have succumbed to the impulse. Having got thus far down the path to death, it may be that the details of suicides, as reported in the papers, will advise them of simple means for ending their lives. It may be said that the opportunities for

suicide offered by a passing train, an open gas-tube, or a silent pool need no writing up to bring them to notice, but none the less the printed accounts of such cases do serve as an actual stimulus. It is impossible not to ascribe to some extent the frequent recurrence of certain methods of suicide to the suggestion afforded by example and by printed record. The fact that a man or a woman has committed suicide in a certain way is likely to be known without newspaper reports in the immediate circle of the event, but it is not here that the sinister influence of example is felt. The evil grows as the influence spreads to a wider population which includes among it a large number of susceptible subjects.

As far as neighbours are concerned nothing would be gained by suppressing the evidence at the inquest. On the other hand, rumour often makes a suicide out of an occurrence which really was an accident, and in this event it may be very desirable that not only the verdict but the evidence leading up to it should be known. The possibility that the public trial of shop-lifters and burglars, to say nothing of other criminals, may suggest a life of profitable adventure to unscrupulous persons has never caused anyone to suggest trying such rogues in camera, or dispensing with the deterrent advantages attached to punishment publicly imposed. We pride ourselves, on the contrary, upon the publicity given, whether to their conviction or their acquittal, as maintaining the national confidence in our courts of criminal justice. The medical profession is interested in the question of wide publicity, chiefly because its members appear as witnesses at practically every inquest that is held, as well as in very many trials arising out of criminal offences. Publicity tends in their case to secure the giving of full weight to their evidence by those before whom it is laid, for a vital witness can much more easily be ignored if no public opinion is there to criticise the proceedings. Publicity also means for medical men the appreciation of their testimony by all members of their profession who may chance to read it. It helps moreover to exclude from the witness-box persons who might otherwise endeavour to pass themselves off as medical witnesses. An unqualified quack would have a much better chance of escaping undetected in camera than he has in a public trial, followed by the publication of his evidence and of the name and address under which he tendered it.

We do not suggest that the publication of columns of scandalous detail not directly bearing upon the cause of death, such as has recently taken place in the case of two women, is of any value to the community. But while we admit the force of the contention that the inquest held in camera could never become an inducement to suicide, we still think that society at large is better served by the existing publicity.

WITH reference to the increased subscription to Fellows of the Royal Society of Medicine living within a mile of the Society's House, the Treasurers of the Society make the following announcement:—

By resolution of a special general meeting of the Fellows, this increase is not to apply to Fellows who have served abroad for 24 months or more, or have been unable to practise on account of war service, until Oct. 1st, 1920.

Fellows who desire to take advantage of this privilege should send necessary particulars to the secretary as soon as possible.

## Annotations.

"Ne quid nimis."

### THE ÆTIOLOGY OF INFLUENZA.

THE recent pandemic of influenza has afforded an opportunity to bacteriologists to review the ætiology of this disease and to investigate it further, an opportunity of which advantage has been largely taken, as a review of our columns in recent months will show. The result is somewhat surprising, since the outcome has been seriously to assail the position previously accorded to the Pfeiffer bacillus, isolated in 1892, as the cause of the disease, and to bring the whole question into the arena of controversy. The Pfeiffer bacillus is still regarded by some authorities as the infective agent, and it is claimed by them that with improved methods it can be found in a very large percentage of cases of the disease. Others again, while accepting its presence in many cases of influenza, assign to it a secondary rôle as contributing to the clinical manifestations or complications of the disease, much in the same way as the pneumococcus and streptococcus are believed to do; and on this view its inclusion in the triple vaccine employed as a prophylactic is justified, even though it is not regarded as the actual exciting cause. One fact seemed early to emerge from the controversy—namely, that in the minds of highly competent bacteriologists there was room for scepticism in regard to the ætiological rôle of the Pfeiffer bacillus, and that at best the critical verdict regarding it must be one of not proven. It was natural, therefore, that research should be more especially directed to two points—one the further investigation of the Pfeiffer bacillus, the other a search for other organisms. A plentiful crop of possible causative agents has resulted, varying from ultra-microscopic filter passers to pleiomorphic cocci. The result at present can be nearly described as confusion, from which, however, we may hope to see some definite results.

An interesting and suggestive contribution to the subject is afforded by a paper which we publish in another part of our present issue by Dr. G. E. Beaumont. He states that he was impressed by the comparative infrequency of the Pfeiffer bacillus and by the pleiomorphism of the organism separated by Donaldson with its possible relation to one of the filter-passing organisms described by other observers. He now records some observations suggesting that influenza is in reality a mycosis, sometimes bronchial, sometimes intestinal, due to a mycotic parasite with several stages in its life-history; and he offers the suggestion that the discordant results of other observers may find their eventual explanation in the pleiomorphic character of the parasite he describes. He is careful to disclaim priority or originality for his observations, pointing out that they are an extension of those of Captain H. J. B. Fry, who described a large spore stage and a hyphal stage in the parasite he isolated from cases of influenza. Dr. Beaumont describes eight forms in the life-history of this parasite—namely, hyphæ, large spores, coccal clusters, small spores, tetrads, mulberry masses, chains of cocci, and bacilli. These forms he has found in varying combinations in films made from the sputum in cases of influenzal bronchitis and broncho-pneumonia, and in the fæces of cases of influenzal

enteritis. The reactions to the Gram-staining method of these various forms appear to be very variable, and this peculiarity was also to be observed in the cultures made on various media from the sputum. These cultures also gave interesting and suggestive results when examined under the microscope, as they, too, showed pleomorphic characters. Although Dr. Beaumont used the various media suggested as specially adapted to the growth of the Pfeiffer bacillus, he was not able to isolate it. He sometimes obtained single colonies which showed characters resembling the Pfeiffer organism, but they were never pure and often contained Gram-positive coccal elements; moreover the Pfeiffer-like organisms would often disappear in subculture. Dr. Beaumont has in addition made a few observations on the urine and blood in cases of influenza, and in the former he has obtained all the stages of the parasite he describes. In the blood in primary cultures he has recovered several of the stages or forms, but only in one case was he able to obtain growths in subculture.

Dr. Beaumont's observations are admittedly incomplete, but they are sufficiently striking and suggestive to require further examination at the hands of other workers. If his results are confirmed and the organism is submitted to and fulfils the full tests of the Koch postulates, then the relation of the various forms of the parasite to one another and to the different organisms found in this disease by other observers will afford interesting matters for investigation and possibly serve, as Dr. Beaumont suggests, to clear up the confusion at present existing by explaining the discrepancies and coördinating the divergent views.

#### PRACTICAL ISSUES OF THE ALCOHOL QUESTION.

THE Medical Research Committee have issued a further report<sup>1</sup> on the alcohol question, in which the main results on manual work and on the coördination of fine muscular movements agree well with those reported previously by Dr. Mellanby. Dr. Mellanby's report (No. 31 of the series) was dealt with in our issue of July 19th in an annotation under the above title. The present investigation was undertaken by Dr. M. H. Vernon, who was assisted by Dr. W. C. Sullivan, Captain M. Greenwood, R.A.M.C., and N. B. Dreyer. Both reports show the important differences between the effects produced by alcohol when taken with or without food, a question which we have pointed out again and again has a practical bearing, and which, Dr. Vernon now remarks, has been curiously ignored by most previous investigators. The Medical Research Committee agrees that the relations between the consumption of food and the physiological effects of absorbed alcohol are so important (as these recent studies show) that much previous work upon the effects of alcohol is now seen to have been impaired in value by disregard of the presence or absence of food in the stomach during the experiments. The influence of alcohol on manual work and on neuro-muscular coördination was investigated in eight men and five women. In seven of the subjects observations were made on the accuracy and speed of typewriting, in three on the accuracy and speed of working an adding machine, and in six on the accuracy with

which a target could be pricked. The administration of alcohol produced some effect in all of the individuals tested by the typing and adding-machine methods, the degree of effect depending largely on whether the alcohol was taken on an empty stomach or with food. On an average it was about twice as toxic under the former conditions as under the latter. In the foodless experiments one subject made 88 per cent. more typing mistakes after she drank 11·2 c.cm. of alcohol. Another subject increased his adding machine mistakes 74 per cent. after taking claret containing 19·4 c.cm. of alcohol; another increased her typing mistakes 156 per cent. after drinking sherry containing 22 c.cm. of alcohol. In some subjects, however, a moderate dose of alcoholic liquid taken with food produced no measureable reaction. Such a non-reactive dose amounted to one glass of port in a male subject and to 4 oz. of port in a female subject. One subject who a year before had been rather a heavy drinker showed little, if any, reaction, even after drinking whisky containing 45 or 60 c.cm. of alcohol. He was tested by the target method and took the whisky three hours after food. In the target method, rows of dots, made on squared paper fixed vertically at arm's length, were pricked at three-minute intervals before and after the alcohol. The average distance of a puncture made from the centre was about 1·8 mm., but after taking 30 c.cm. of alcohol the target-pricking error increased 12 per cent.; after taking 37·5 c.cm. it increased 43 per cent., and it continued to increase in arithmetical progression with the dose of alcohol till it was 132 per cent. above the normal when 60 c.cm. were taken. To sum up, this inquiry would seem to endorse by scientific measurement what has been recognised for a long time in practice. The creature of addiction, or one who has acquired the habit of moderate alcohol consumption, shows a negligible result to moderate doses of alcohol according to the tests here applied. In other words, the body has a remarkable power of adapting itself to acquired habit. Then, again, according to these experiments, alcohol taken on an empty stomach proves to be twice as toxic as when taken with food. Alcohol consumers found this out long ago, for the munching of a biscuit with a glass of wine between meals is a very old and familiar practice. Man seems to have discovered instinctively that food tempers the action of the spirit.

#### GONOCOCCUS PNEUMONIA.

Dr. Martin Ross,<sup>1</sup> of New York, records the following case, which he regards as one of gonococcus pneumonia. The patient was a girl, aged 16, suffering from an acute exacerbation of an old gonorrhœal infection superimposed upon a dysmenorrhœa. Lobar pneumonia developed and followed an atypical course. The sputum was scanty and milky white in colour, with no trace of blood in it at any time. Pure cultures of Gram-negative, biscuit-shaped diplococci were obtained from the sputum, the blood, and the lung. Post mortem both lungs were found riddled with minute abscesses, there was consolidation of the upper left lobe; in the lower lobe of the right lung there was a large abscess cavity and a smaller abscess in the right upper lobe. The occurrence of gonococcus septicæmia in this case was probably due to the presence of

<sup>1</sup> Special Report Series, No. 34. National Health Insurance, Medical Research Committee: The Influence of Alcohol on Manual Work and Neuro-muscular Coördination. London: Published by His Majesty's Stationery Office.

<sup>1</sup> Medical Record, 1919, xcv., 950-2.

dysmenorrhœa with the damming up of the menstrual flow. In spite of the relative frequency of gonococcus septicæmia with metastases, Ross could only find one other case on record of gonococcus pneumonia, which was reported by von der Bressel in the *Münchener medizinische Wochenschrift* in 1903. The patient, a man aged 32, while under treatment for gonorrhœa developed signs of lobar pneumonia with scanty, milky white, bloodless sputum. Pure cultures of Gram-negative diplococci were obtained from the blood and sputum. In a week's time the temperature fell by lysis, and complete resolution took place on the eighteenth day.

#### THE CASE OF BUBONIC PLAGUE IN LIVERPOOL.

THE Ministry of Health make the following announcement concerning the fatal case of bubonic plague in Liverpool to which reference was made in our last week's issue. The patient, a master stevedore and bargeman, was removed to the isolation hospital on July 11th and died on July 19th, but bacteriological confirmation of the fact that he was suffering from plague was not obtained until July 26th. No further cases have occurred. Dead rats have been discovered in the patient's office and in the adjacent premises, but on examination none were ascertained to have plague. A mouse found dead has been proved by bacteriological examination to have suffered from plague. The corporation have undertaken the disinfection of the premises and the destruction and examination of rodents found in them. One of the medical officers of the Ministry is engaged on a detailed investigation of all the circumstances of the case.

#### THE NEW PUBLIC HEALTH ACT IN SOUTH AFRICA: CONSCIENCE CLAUSE ABOLISHED.

THE new Public Health Act, No. 36, 1919, of the Union of South Africa, was recently promulgated at Capetown. The Governor-General has, under the Act, appointed Sir Thomas Watt, K.C.M.G., Minister of the Interior, to hold the portfolio and administer the Department of Public Health in addition to the Department of the Interior and the Public Works Department. It is also announced that from July 1st, and until further notice, the Department of Public Health established under Section 2 of the Act administers all matters relating to (a) public health, (b) adulteration of food and drugs, (c) district surgeons, and (d) medical councils and pharmacy boards, instead of, as heretofore, the Department of the Interior. The Public Health Bill in its passage through the Senate was subjected to one radical alteration—the deletion of the antivaccination conscience clause—and this alteration was accepted by the Assembly and has become law. Sir Thomas Watt submitted to the Senate, when the conscience clause was under consideration on June 2nd, that a reasonable case had been made out for such a clause, but the Senate deleted the clause by 13 votes to 8. Eight days later the Assembly accepted the deletion of the conscience clause by 48 to 26, although it had been originally carried by the popular House by 61 votes to 19. One argument that evidently weighed with the Assembly was that under a conscience clause there would be nothing to prevent whole tribes of natives or coloured people raising objections to vaccination. Sir Thomas Watt also stated that in the six years before

the war there were only four cases of small-pox in Germany, where vaccination was compulsory "even in the case of people with a conscience." According to Dr. John Hewat's statement in the Senate, 40 per cent. of the people in the Orange Free State are unvaccinated, and the senior elected member of the Colonial Medical Council is not likely to make loose assertions on such a matter. The Act also provides for a refund by the Government of 50 per cent. of all expenditure on public health incurred by municipalities, a clause with obvious bearing upon the State treatment of tuberculosis. While the measure was in the Senate Dr. Hewat urged the Government to deal with tuberculosis sanatoria from a national point of view, instead of leaving it to the municipalities to contribute half of the cost. Sir Thomas Watt claimed that the measure went a long way towards the nationalisation of the care of public health. It had been asserted that the Government spent more money on dealing with diseases of stock than on public health, but the Minister declared, on the contrary, that the Government spent £10 on public health as compared with £1 spent on animals. Dr. Hewat said that the cost of the measure was not going to be great—only £80,000 or £100,000 per annum—and appealed to the Government to increase the refund of 50 per cent. on expenditure made by municipalities in connexion with public health. This request being declined by the Minister, Dr. Hewat said he deplored the decision of the Government, especially in reference to the need for tuberculosis sanatoria.

#### RESECTION OF ANKYLOSED FINGERS.

IN the *Journal de Médecine de Bordeaux* M. H. Lefèvre has called attention to an improved method of treating ankylosed fingers, such as follow bullet wounds, which should prove useful, especially at the present time. These wounds, if they do not lead to immediate amputation, terminate in ankylosis, usually in extension, frequently with the ankylosed finger overriding its neighbour. The overriding is due to partial loss of articular surface, whether condyle or socket. Such ankylosed fingers are useless, subject to numerous injuries, and interfere with the function of the next fingers. The usual treatment is amputation. One day, after amputation of an ankylosed finger, which he considered useless, M. Lefèvre asked himself, Can nothing better be done? On dissection he found the flexor tendons intact, the extensors adherent to the skin and the bones but without solution of continuity. They had been divided by a shell fragment, but the ends were united by fibrous tissue. Having broken down the ankylosis involving the first interphalangeal joint and freed the tendons, he could, by traction on them, flex and extend the phalanges on one another. He therefore decided to resect the next ankylosed finger that he encountered with the tendons intact. But in three cases in which he operated he could obtain no indication on this point beforehand. Only the operation gave this. Wound of finger-joint is frequently accompanied by articular fracture and suppuration, and the resulting ankylosis by peri-articular lesions. In the end the tendons and soft parts are more or less altered, if they are not initially. Whatever the degree of disability, it is the condition of the tendons that matters. Whether they are ruptured or adherent the result is the same—complete immobility of the phalanges on one another or on the metacarpal bone. Before sacrificing such a

finger M. Lefèvre thinks that the surgeon should make sure by exploratory incision of the state of the tendons and not amputate unless they are irreparable. He relates three cases in which he resected the finger with success. The following may be taken as an illustration. A man, aged 32 years, was wounded on Jan. 17th, 1915. He was admitted to hospital on the 20th with a sloughing wound of the first interphalangeal joint of the right index. At the end of February cicatrization was complete. In April he came under the care of M. Lefèvre. The joint was ankylosed in extension and the index overrode the middle finger. Radioscopy showed that this was due to loss of the internal condyle of the first phalanx. On the dorsal and internal surface of the finger there was adherent scar. The palmar surface of the second and third phalanges rested on the dorsal surface of the middle finger. The patient could not effect any movement of flexion of the phalanges on one another, or any movement of flexion or extension on the metacarpal bone. He therefore asked for amputation. On April 8th a longitudinal incision down to the bone was made on the external surface of the finger. With a rugine the soft parts were raised from the dorsal and from the palmar surface. The fibrous and osseous tissues constituting the ankylosis were divided. The cartilaginous surfaces had disappeared. In the centre of the glenoid cavity of the second phalanx was a little focus of osteitis with granulations. Curetting was performed and a new cavity was modelled. The external condyle was resected so as to level the end of the bone. With a gouge a new head was modelled. Two sutures were inserted in the fibrous tissues. Adhesions between the skin and the fibrous tissue, which surrounded the extensor tendon, were broken down. The cutaneous wound was sutured. Next day passive movements were begun. On June 26th the patient could completely extend and almost completely flex the finger. He could roll a cigarette and button his clothes. The finger was simply a little shortened. When seen again in February, 1917, he had good use of the finger.

#### SCIENCE AS MADE IN GERMANY.

EVEN in the days when it was customary to take German scientists at their own valuation doubt would at times arise as to whether or not these gentlemen were quite so altruistic and so devoted to the cult of philosophy for its own sake as they held themselves out to be. A wise commentary on their attitude is contained in an excellent series of articles on the Pan-German Internationale by Mr. Adolphe Smith, which appeared in the *Times* at the end of July. Mr. Smith, whose forcible writing on many subjects of vital importance to medicine is familiar to all readers of THE LANCET, writes as follows:—

"The danger or otherwise of consuming tuberculous meat was of very material importance to the German Agrarian Party, for a large proportion of German cattle was known to be tuberculous. This party held office when at a great international scientific congress it was my good fortune to discover and to denounce intrigues that had for their purpose the adoption of a resolution exonerating the specific germ of bovine tuberculosis. This manoeuvre had been promoted by the German delegation and the official representatives of the German Government."

The accuracy of the statement emerges from the report to THE LANCET of the International Congress on Tuberculosis held in 1908 at Washington, and it brings to light an aspect of German duplicity for

which, even after the experience of the past five years, we confess that we were unprepared. Mr. Smith's protest against German methods at this Congress was printed in very similar words in our own columns 11 years ago. Those whose memories carry them back to the year 1901 will recall the profound sensation caused by the statement made by Koch before the British Congress on Tuberculosis in reference to this same topic.

"The infection of human beings (by bovine tuberculosis) is a very rare occurrence. I should estimate the extent of infection by the milk and flesh of tuberculous cattle, and the butter made from their milk, as hardly greater than that of hereditary transmission, and I therefore do not deem it advisable to take any measures against it."

It was charitably supposed that the distinguished scientist had slipped into error. No doubt he had, but we may perhaps be forgiven for wondering if the exact nature of the error was correctly diagnosed at the time.

#### HEREDITY AND MENDELISM IN PTOSIS.

A REMARKABLE family has been discovered in America in which the inheritance of ptosis can be traced through six generations.<sup>1</sup> Living in a sparsely settled country, this family, though seldom intermarrying, have remained in the same district for a century and a quarter. The recorder, Dr. Briggs, of Asheville, North Carolina, gives statistics of 128 members of 23 families (or "sibships," to use Nettleship's term), all descended from one Martin Maney, an emigrant from Dublin and a veteran of the Revolutionary War. In each of these 23 sibships one or more members were affected with ptosis, and, taking them all together, the numbers of the affected and unaffected were exactly equal, 64 of each. The evidence in most cases rested on hearsay and family tradition, but the condition was seen and photographed in six members of the last three generations, and with regard to the others, in the case of such an obvious defect, family tradition can probably be trusted. The equality in numbers between the affected and unaffected points strongly to the inheritance being in accord with the Mendelian theory, although the precise equality in this case must be accidental, for the theory postulates equality not between the number of affected and unaffected developed individuals, but between the number of potential individuals contained in all the germs, both developed and undeveloped, originally possessed by the members of the affected sibships. Perhaps even more striking than the equality in numbers is the fact of the inheritance being continuous in every case but one—i.e., there was no affected individual with both parents normal, and in every case (but one) of both parents being normal none of the progeny were affected. We may, perhaps, suppose that in the exceptional case a slight degree of ptosis had been overlooked by the family; at any rate this is what the recorder suggests (though in that case the equality before mentioned would no longer be exact). To explain the facts on the Mendelian theory it must be assumed that the character of ptosis is a dominant one in relation to the normal character, which is recessive. The ancestor of the first generation was an impure dominant—i.e., he was affected himself with ptosis, but while one-half of his germ cells contained the ptosis factor the other half did not. The result would be that of his children roughly one-half would be affected with ptosis, while the

<sup>1</sup> American Journal of Ophthalmology, June, 1919.

other half, developed from germs completely free from the ptosis character, would be normal. Every affected member of the genealogy would be like the ancestor of the first generation, an impure dominant, and, as the result of a marriage with a normal partner, would transmit the character of ptosis to, roughly, one-half of his or her children, while unaffected members of the genealogy would transmit no taint. This is what happened in the family in question, so far as we can tell from the not very full data supplied. The record is one of extreme interest, and should be compared with the work of the late Mr. Nettleship, whose observations on the bearing of the Mendelian theory on various eye diseases are summed up in his Bowman lecture for 1909.<sup>2</sup> It is here shown that while the facts of some hereditary conditions in humans cannot be interpreted on the Mendelian theory except by the assumption of various modifying influences there are other hereditary conditions in which they can. The best example of the latter is found in hereditary forms of cataract, whether noticed first at birth or in later life. Most cases of senile cataract occur apart from heredity, but there are some families in which there is no doubt that the liability to the disease is inherited, and in these it is very rare to find an affected member one of whose parents was not also affected. In the case of congenital cataract the inheritance is practically always of the continuous type, and in affected families (sibships) a rough approach to equality between affected and non-affected members will be found on the average. The factor causing cataract, therefore, behaves as a dominant towards the normal, and we may predict with some confidence of an affected member of such a family that in the case of children being born to him or her the chance of their inheriting the disease will be an even one, while in the case of a non-affected member of the same family, provided that the second parent is normal, the chance of inheritance is practically nil. Several pedigrees of families with retinitis pigmentosa have also been put on record, and in the majority of them the inheritance is continuous, the disease factor behaving as a dominant; but in some of these pedigrees the inheritance is discontinuous—i.e., interrupted by a healthy generation, and it is possible that in these pedigrees the disease behaves as a recessive. In the case of some other diseases—e.g., Leber's hereditary optic atrophy—the interpretation of the facts is complicated by a new factor—sex limitation. It is only when there are no complicating factors that we can expect to find the Mendelian theory illustrated, but the instances where this has already been done to some extent are sufficiently numerous to encourage those interested in the subject who have the opportunity of collecting pedigrees bearing on the point to persevere.

<sup>2</sup> Trans. Ophthalmological Society, vol. xxix.

**THE POTASSIUM COMPOUNDS ORDER.**—By an Order issued by the Minister of Munitions dated July 31st, 1919, the operation of the Potassium Compounds Order, 1917, as modified by an Order (Partial Suspension) issued in 1919, is suspended on and after August 1st, 1919, until further notice. The original Order set forth that no person may offer to purchase or take delivery of certain potassium compounds except in accordance with the terms of a licence restricting the quantities permitted to be dealt with. Shorn of legal verbiage, the new Order means that the restrictions then indicated are now removed, and it is cited as the Potassium Compounds (Complete Suspension) Order, 1919.

## A CONFERENCE ON PEDIATRICS.

### I.—THE MEDICAL ASPECT.

FOR some time past the subject of pediatrics has been occupying the minds of those who have at heart the health and welfare of infants and young children. More especially have they been concerned with the question of the teaching of the normal physiology as well as the pathological conditions of childhood to medical students, for it is said that the newly qualified practitioner is turned out with some knowledge of disease as it occurs in children, none of the healthy child, and the haziest notions about the feeding of infants.

An informal conference was held last spring to consider generally the subject of pediatrics, under the chairmanship of Sir GEORGE NEWMAN, K.C.B. Advantage was taken of the presence in this country of specialists from America and the colonies to ascertain the results of their experience of maternity and child welfare in relation to the medical curriculum. The conference did not receive at the time the attention that it deserved.

Dr. W. R. RAMSEY, associate professor of diseases of children, University of Minnesota, described

#### *The Position of Pediatrics at the University of Minnesota.*

Here there is a separate department with 30 beds, a whole-time professor at the head, and an associate professor and staff of clinical assistants, most of whom are half-time men. Until four or five years ago pediatrics was a separate professorship, but was under the department of medicine. It was soon realised that the subject must be taught intensively, and that to teach a subject intensively there must be a separate department. In Minnesota there is very close coöperation between pediatrics and obstetrics. Both departments are on the same floor, and as soon as the cord is tied the child is passed over directly to the department of pediatrics. The normal infant is regarded as of vital importance in the teaching of the student, for it is realised that if he knows the normal infant thoroughly he quickly recognises the abnormal one. Dr. Ramsey mentions three fallacies which are still prevalent amongst medical men: (1) that the baby must be bathed immediately after birth; (2) that the baby's mouth must be swabbed out daily; and (3) that a dose of castor-oil should be given on the third day. Dr. Ramsey also remarked on the many and various opinions which were rife on the subjects of infant feeding and hygiene. In the United States it was found necessary to appoint a commission of representative pediatricians to formulate a scheme to which all might subscribe. As the result a pamphlet was drawn up and issued by the Government in many hundreds of thousands. The findings of these men are now accepted as the basis for a uniform propaganda for child feeding and general hygiene to be applied to children.

#### *The Teaching of Pediatrics in Canada.*

Dr. G. S. STRATHY (Lieutenant-Colonel, C.A.M.C.), assistant physician, Hospital for Sick Children, Toronto, described the condition of affairs in that city as it was when he was there four years ago. The teaching of pediatrics, he said, had changed considerably in Toronto in the last decade.

About ten years ago the teaching of this subject was put in special hands and taken up from two points of view—the teaching of medical people and the teaching of the public. The former is divided into two parts—the teaching of the medical student and the teaching of the practitioner. The student has had to undergo a five years' training, but this is now to be increased to six years. In the fifth year there are practically no lectures to attend, all the time being spent in the wards and laboratories. Each student gave three months to specialties, six weeks of which was given to pediatrics. He attended for two hours a day on three days a week. The Children's Hospital in Toronto contains 150 beds, 50 of them being devoted to children under a year. Some of the students live in the hospital and assist the house staff in their work; all attend the out-patient clinic, weighing the babies week by week and, if necessary, following them up in their own homes. At the Hospital for Sick Children the pediatrics division is responsible for the children from birth to 18 months, the

medical division from 18 months to 14 years. The education of the practitioners is largely done in association with the municipal authorities.

Dr. J. G. ADAMI, professor of pathology, McGill University, Montreal, gave an account of Canadian provisions in general, Canada, as he said, holding a half-way position through having partly British and partly United States influences acting upon it, and being sensitive to both. Ever since the McGill University was opened in 1824 the medical school has followed the British system of having the free entry of the students into the wards, bedside teaching in maternity work, as well as in medicine and surgery, being a striking characteristic. In pediatrics there is a professor, three lecturers, and two demonstrators, the size of the staff being due to the fact that there are out-patient clinics for children at both of the two main hospitals attached to the University, the Royal Victoria and the Montreal General Hospitals, as well as at the Maternity Hospital. In all these pediatrics is taught. An extra year is now being added to the curriculum, and still more work on this subject will be done. According to the McGill Calendar for the 1916-17 session—

"A didactic course on the diseases of infancy and childhood, including the feeding of infants, is given during the session to students of the fourth year. Clinical and didactic lectures are given on diseases of the new born at the Montreal Maternity Hospital. In the Montreal General and Royal Victoria Hospitals weekly clinical lectures and ward demonstrations on diseases of childhood will be given to students of the fifth year, and groups of students in rotation will be assigned work in connexion with the out-patient children's departments of both hospitals. The new Foundling and Baby Hospital, which has recently been opened, with a capacity of 100 beds, will be utilised during the session for a series of demonstrations in infant feeding."

An extraordinarily strong point is made of infant feeding. In the Maternity Hospital the children are taken away from their mothers as soon as they are born, and those infants are looked after mainly by the pediatricians, so much so that one of the leading obstetricians absolutely refuses to see the child. He adopts the "by-product" idea, and says that his whole concern is with the mother, to see that she is well through maternity, and that the child should be, from the first moment of its life, in the hands of the physician who is going to look after it during the next two or three years.

#### *A Children's Department at Guy's Hospital.*

Dr. H. C. CAMERON described the scheme for a complete children's department as accepted by the governors of Guy's Hospital and now in process of completion. It is best described in his own words:—

The children's wards, containing about 50 cots, will be in close proximity to a lying-in ward of 20 beds. The infants born in the lying-in ward will be under the care of an assistant, who will act under the joint control of the obstetric surgeons and myself. The Salomon's Centre for Infant Welfare is housed in a building adjoining the hospital, and is approaching completion. It will be conducted by assistants acting under my control. The centre will undertake the ante-natal care of the two to three thousand expectant mothers who apply each year to the hospital for assistance in childbirth. These births are attended in part by the students of Guy's Hospital, and in part by the pupil-midwives of the midwifery school attached to the hospital, in each case under the necessary supervision. The mothers all live in an area which is situated in the boroughs of Bermondsey, Southwark and Lambeth, and our arrangements have the approval of the medical officers of health concerned. In this area there are some 12 other infant centres at work, and the Salomon's centre has entered into arrangements with these centres to cover the whole area completely, so that every child is sent to the centre which is most conveniently situated to its home. The Salomon's centre, therefore, although it conducts the ante-natal work for the whole area, restricts its post-natal work to a small district in the immediate neighbourhood of the hospital.

The out-patient children's department has made arrangements to place the resources of the hospital both for diagnosis and treatment at the disposal of all these centres. In the Salomon's centre there will be a resident superintendent and six resident health visitors. They will be assisted in the work by the pupil-midwives, and ultimately, it is hoped, by students working for a diploma in infant welfare. The medical students of Guy's Hospital will have opportunities of studying the work and appreciating its methods and objects. An arrangement has just been made by which all students will spend three months in the children's department, passing into it immediately after three months spent in the special study of midwifery and the diseases of women, and I feel that with these arrangements it will be possible to make the instruction sufficiently comprehensive so that it may include the study of the newly born and of the normal child as well as the study of sick children.

#### *Pediatrics in the Medical Curriculum.*

Dr. Cameron points out that one of the difficulties which beset the teacher in his endeavour to give the student a sufficient training in pediatrics is that the subject is a voluntary one, and there is no set examination of his knowledge as part of the final examination. The training should be compulsory, and an examination must be held which will

demand that the student shows the same knowledge of infant management and hygiene as is expected of him in his answers on morbid anatomy and clinical symptoms. In order to afford time for the amount of study necessary Dr. Cameron suggested that the curriculum should be relieved on the anatomical detail side and on the surgical assistance side. Something might also be done in cutting out a good deal of bacteriological technique. He urged that the University of London should grant an M.D. degree in pediatrics, as is done now in midwifery and diseases of women.

As the CHAIRMAN said concisely, Dr. Cameron suggests (1) that a pediatric department is necessary in every medical school; (2) in this department every student shall be taught compulsorily for three months; and (3) every student shall have a special and separate examination in pediatrics.

Dr. J. S. FAIRBAIRN pointed out that any suggestions with regard to examinations, in order to be effective, must come from the General Medical Council. The examination system should be arranged to meet the new conditions of things; every medical school should have a complete centre; the student should take the midwifery course and, if possible, go straight on from midwifery into pediatrics, watch the life and health of the infant whose intra-uterine development and birth have hitherto been his care, through its breast-feeding and weaning. If the student does that he gets a complete picture of the whole thing from the preventive medicine point of view. It is the normal infant that should be taught to the student. The pediatrician should approach the subject from the standpoint of physiology rather than of pathology.

Dr. EARDLEY HOLLAND was strongly in favour of the infant being handed over to the pediatrician for the purpose of teaching and research in the hospitals and medical schools. If the obstetrician has to look after the infant and to study it intensively, he must give up gynaecology; he cannot do both. He must either be an obstetrician and pediatrician, or he must be an obstetrician and gynaecologist. But obstetrics ought not to be separated from gynaecology. It is agreed that they are inseparable subjects. Dr. Holland considers that, except in a few chosen places, the teaching of obstetrics is exceedingly badly done. As he says:—

Nearly all the lying-in beds for teaching are allocated to the teaching of the midwife, and the student is left out in the cold. It is absolutely essential that lying-in beds in the general hospitals should be established, and that it should be made obligatory upon the student to do lying-in work in a ward. I mention this because it is closely connected with pediatrics; for it means the study of the fetus, the causes of foetal death, the relation of the fetus to the infant, injuries received by the fetus, and the diseases transmitted to the fetus during pregnancy. I feel that as obstetricians we have very little more interest in the infant than is included in the foetal stage. The part that should be played by the obstetrician in infant welfare is to look after the fetus; to preserve it during pregnancy from transmitted disease, and to preserve it during labour from the injuries it may receive during its passage through the birth-canal. As soon as the establishment of pulmonary respiration has announced the fact that the metamorphosis from fetus to infant is complete, he will hand over the infant to his pediatric colleague, asking the latter to note that it has been delivered to him in good condition.

It has only been possible, so far, to consider the opinions which were brought forward by some of the members of the Conference on the teaching of the medical student. The following is an account of the discussion of the social aspect.

## II.—THE SOCIAL ASPECT.

### *The Importance of Breast Feeding.*

Dr. W. R. RAMSEY laid stress on the importance of breast feeding, and described the change which had lately taken place in American opinion, both lay and medical. A few years ago, he said, not more than 30 to 40 per cent. of American women nursed their children. The country was flooded with literature on patent foods, which was sent to women not only after the baby was born, but long before, pointing out the simplicity of artificial feeding. Doctors and nurses became imbued with the same opinion, and as a result the public thought that breast feeding was practically an impossible thing. At the present time in many communities 75 to 80 per cent. of even well-to-do women nurse their babies and are proud of it, instead of regarding it as a disgrace. As he puts it, "they discuss it at their circles and their card parties, and go home promptly to nurse their babies." In order to eradicate the heresies which have been handed down from time immemorial we must first educate the doctors and nurses, and then the public will become educated; or else we must educate the public first, and the doctors will be compelled to follow suit.

*Infant Welfare in Toronto.*

Lieutenant-Colonel STRATHY described the state of affairs in Toronto. The healthy babies are looked after at milk depôts, each serving a district, of which there are 16 in Toronto, for which the municipality is responsible. To each of these depôts a practitioner is attached, who attends twice a week. The city authorities supply the premises for the clinics, and the nurses who attend there and who follow up the children. Within 10 days of the birth of the baby, whether the family be wealthy or poor, the nurse from the City Hall calls at the house to offer help or advice to the mother. In the poorer districts she is usually welcomed and asked to call again. The mother is encouraged to go to the depôt and have the baby weighed each week, and it is found now that she can do this without hurting the feelings of the practitioner who is looking after that baby, though at first they had to be careful not to tread on the toes of local practitioners. As long as the baby is healthy and advice is needed only in the matter of feeding, it is treated at the depôt, but sick babies are sent to the children's hospital with a card. A card index is kept for all babies, and after treatment at the out-patient department of the hospital the baby is sent back to the depôt, together with its card, showing all the treatment it has had. A nurse is always present with the doctor who holds the clinic, and will always supply a report of the home conditions when required. For those who attend the out-patient clinic any home treatment, such as washing out the stomach, can be carried out by the nurse; instructions go to the City Hall to the head nurse, and a nurse is instructed to go and do it. There are about 150 nurses carrying on this work who have graduated at the children's hospital.

*Infantile Tuberculosis in Italy.*

Captain R. A. BOLT gave a brief outline of some of the findings of a Commission which was sent to look into the tuberculosis situation in Italy, and which was part of the American Red Cross in Italy. It was found that tuberculosis was very closely related to other problems, and the report which they issued, which was drawn up by Captain Knud Stonman, statistician of the Commission, is chiefly concerned with infantile mortality in Italy during the war and with the child-welfare aspect of the problem. In Italy, prior to the war, the infant mortality rate was gradually being lowered as industrial prosperity increased, especially in those places where serious efforts in child welfare had been made. The Italians had developed a system of institutions through their pediatricians which in most places met the immediate needs of sick children, had recognised the need for a good milk-supply for growing children, and, through a system of marine and mountain colonies, had provided recreation and outdoor life for those who were weak and predisposed to tuberculosis. In a number of medical centres of Italy, prior to the war, special instruction was given in pediatric clinics, but only in a few was the socio-economic side of child-welfare work emphasised and opportunity given to the students to do practical work in milk stations, consultations, and infant welfare centres. In Italy breast feeding of infants has always been in favour, and in the north from 85 to 90 per cent. of the children are breast-fed for one year at least, and in the south from 90 to 95 per cent. The midwife service is satisfactory, midwives being required to take a two years' course of training in medical centres, after which they take their diploma. In Italy the incidence of puerperal infection is comparatively small, and the amount of ophthalmia neonatorum relatively so. On the outbreak of war some of the obstetricians and pediatricians were drafted into war service and a number of children's hospitals were utilised for war purposes. The birth-rate increased up to about nine months after mobilisation, and since that time there has been a steady and, in some places, an alarming decrease, the national birth-rate falling from about 30.5 per 1000 at the outbreak of war to something like 18 or 16. With this decrease in the birth-rate there has been an increase in infant mortality, especially during the winter and summer, most marked in January, February, and March, and in June, July, and August. The death-rate of children from 1 to 5 years has increased much more rapidly, which has been attributed to the unsuitable food given to young children after weaning owing to the difficulty of procuring suitable food because of the high prices. The death-rate from

influenza was particularly high amongst babies and young children, young women between 20 and 30 years of age, and pregnant women. Abortion occurred very readily.

In the North of Italy considerable progress has been made in the organisation of infant welfare work, and although the birth-rate is lower than that of the Adriatic coast and in the south, they have managed in the large centres to reduce the infant mortality rate, so that there the actual saving in life has probably been greater. The smaller towns along the Adriatic have suffered severely from the cutting off of trade and fishing, and of the influx of the rural population into the cities. Women were drawn into the various industries, and often left their children to be looked after by those who did not know how to direct the feeding properly. There has been, in consequence, a considerable increase in deaths from gastro-intestinal diseases in the provinces along the Adriatic coast from Rimini to Lecce. During the war there has also been a considerable increase in the number of deaths from tuberculosis, and tuberculosis among children under 10 years of age is also on the increase. The increased cost has prohibited the middle classes from procuring wet nurses. The death-rate among the wet nurses' own babies has also been high. There has, apparently, been no increase in the number of foundling asylums and illegitimate babies. The mortality, however, among the illegitimate babies has been about twice that among the legitimate children, and under the best conditions in the foundling asylums the mortality has been greater. In order to meet all these problems milk-distributing stations and economic kitchens have been established in every large centre, and considerable amounts of condensed milk have been distributed by the Red Cross. Clothes and institutional care have also been provided, but there has never been in Italy any enthusiasm for health visitors, and up to the present time the people neither understand nor appreciate the importance of trained health visitors. During the war a considerable number of intelligent, well-to-do women entered the nursing service in the Army with the Italian and American Red Cross, and have had their eyes opened to the needs of the civil population, especially to the care of the babies. From this group of women it is hoped to gather nuclei here and there for instruction in public health nursing. The coördination of all the child-welfare activities in various centres must also take place, and in order to become effective a national organisation, with an executive committee representing various types of work for children, should be organised. In Italy there is growing a healthy idealism for maternity and child welfare. The men and women with children are looked upon as having real assets, economic, social, and religious. The committee has been able to supply nurses to give secretarial help and to help with regard to publicity.

*The Position in England.*

Speaking of the situation in England, Captain Bolt considered that three things would have to be done. The most important was the education of the medical student to the needs of infant-welfare work through the pediatric departments. The next was the training of health visitors along broad social, economic, and nursing lines, though not necessarily very intensive. Thirdly, there was the need of educating the growing generation of mothers to the necessity for this type of work, which could most easily be done in the upper grades of the schools. In Cleveland a scheme was introduced whereby elementary courses on infant hygiene were given, school nurses taking one course and domestic science teachers the other. Mothercraft in schools should be taught not by regular day school teachers, but by those who are specially familiar with the health side of child problems. The health visitor can teach the importance of proper feeding and the proper care of milk, can impress upon the school children why the babies are dying, and can urge the necessity for breast feeding. Teaching should be given to children between the ages of 12 and 14, and should be compulsory. The health visitor should have a thorough training in general nursing before she takes up her public health duties. In Cleveland all the nurses connected with the health department have had a general hospital training, a special training in tuberculosis dispensaries, sanatoriums, &c., or in infant welfare centres, children's hospitals, and dispensaries. From an infant-welfare point of view, social service should receive more stress than long preliminary hospital training.

*A Baby Hospital in New Zealand.*

Dr. TRUBY KING described what had been done in New Zealand. A small hospital was established solely as a baby hospital, and nurses were trained to fit them for teaching and for the care of the mother and child throughout the whole country. The Society for the Health of Women and Children was started as a purely voluntary organisation; monthly reports are issued to the Public Health Department, and the society has worked in loyal co-operation with them. There has been a growing recognition upon the part of the public authority. At first there was no grant towards the voluntary funds of the society, but now the Government contributes 24s. for every pound raised voluntarily for the salaries of mothercraft nurses, and grants generous annual subsidies towards the support of the hospitals established by the organisation. The nurses are allowed to travel free of cost over the State-owned railways, and the municipalities give them free travelling over the municipal tramways.

*Resolutions Approved.*

The following important resolutions were unanimously passed:—

- (1) That every effort should be made to impress on the whole community the supreme importance of breast feeding, for the sake of both mother and child; that at present over-feeding of the baby, especially in the first fortnight of life, is one of the commonest and most serious mistakes of nursing mothers, often upsetting the child and leading to the early abandonment of suckling.
- (2) This tendency can be best counteracted by a general recognition of the benefit of greater regularity and lessened frequency of feeding than is customary.
- (3) With very few exceptions nursing only every four hours from birth is best for mother and child, though in a few cases more frequent feeding may be desirable.
- (4) That in general there should be an interval of seven or eight hours between the last feeding at night and the first feeding in the morning.
- (5) That every medical student preparing for a registrable qualification shall receive adequate teaching in the subjects of infancy and childhood in health and disease; that attendance in a department where instruction is given in these subjects should be compulsory for a period of not less than three months and that some special part of the final examination in medicine should be devoted to these subjects.
- (6) That, as far as practicable, this study shall follow upon, and be coordinated with, a satisfactory course in obstetrics and gynaecology, and should be made available for post-graduate students; that the present training in obstetrics leaves much to be desired, especially in regard to the lack of facilities for bedside teaching in midwifery.
- (7) Great public advantage would result from a larger measure of uniformity in the advice given by public authorities and others in respect of maternity, infant, and child welfare; the only way in which we think this can be secured is by obtaining a written statement from a body of experts.
- (8) Both practical and theoretical instruction in infant hygiene should form a part of the training of midwives and of all persons engaged by public authorities in infant welfare work.
- (9) That maternity nursing should only be undertaken by competent and adequately trained persons, preferably by qualified midwives.

## URBAN VITAL STATISTICS.

(Week ended August 2nd, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 10.1, 9.0, and 10.3 in the three preceding weeks, fell to 9.7 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 9.5, or 1.0 per 1000 below that recorded in the previous week, while among the remaining towns it ranged from 2.7 in Acton, 2.9 in Carlisle, and 4.0 in Rotherham, to 15.5 in Stockton-on-Tees, 16.3 in Southampton, and 17.2 in Exeter. The principal epidemic diseases caused 154 deaths, which corresponded to an annual rate of 0.5 per 1000, and included 69 from infantile diarrhoea, 45 from diphtheria, 20 from scarlet fever, 10 from whooping-cough, 6 from enteric fever, and 4 from scarlet fever. Measles caused a death-rate of 1.2 in Newcastle-upon-Tyne. There were 2 cases of small-pox, 1538 of scarlet fever, and 1117 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2, 1526, and 1140 respectively at the end of the previous week. The causes of 31 deaths in the 96 towns were uncertified, of which 5 were registered in Birmingham, 4 each in Liverpool and South Shields, and 3 each in London and Manchester.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 11.0, 10.6, and 11.1 in the three preceding weeks, fell to 10.6 per 1000. The 227 deaths in Glasgow corresponded to an annual rate of 10.6 per 1000, and included 6 from measles, 5 from infantile diarrhoea, 2 from whooping-cough, and 1 each from enteric fever and diphtheria. The 72 deaths in Edinburgh were equal to a rate of 11.2 per 1000, and included 4 from measles and 1 each from scarlet fever, whooping-cough, and diphtheria.

*Irish Towns.*—The 92 deaths in Dublin corresponded to an annual rate of 11.8, or 0.3 per 1000 above that recorded in the previous week, and included 4 from infantile diarrhoea. The 79 deaths in Belfast were equal to a rate of 10.3 per 1000, and included 2 from infantile diarrhoea and 1 from diphtheria.

THE King has approved the retirement of Lieut.-Col. F. P. Maynard and Lieut.-Col. S. H. Henderson from the Indian Medical Service.

## ROYAL COLLEGE OF PHYSICIANS OF LONDON.

*Comitia of the College.*

AN ordinary Comitia of the College was held on July 31st, Sir NORMAN MOORE, the President, being in the chair.

On the report of the Censor's Board it was resolved—

"That Arthur Edward Gladstone be declared to be no longer a Licentiate of the College, that he forfeit all rights and privileges of a Licentiate, and that his name be removed from the List of Licentiates during the pleasure of the College."

Dr. Frederic Percival Mackie was admitted to the Fellowship of the College.

The following, having passed the required examination, were admitted as Members:—

Thomas Beaton, M.D. Lond., L.R.C.P.; Cecil Clinton Birchard, M.B. Toronto; Reginald St. George S. Bond, M.B. Elin.; Maurice Davidson, M.D. Oxf., L.R.C.P.; Alan Worsley Holmes a Court, M.B. Sydney; Arthur Edwin Horn, M.D. Lond., L.R.C.P.; Sydney Fancourt McDonald, M.D. Melb.; Douglas Murray McWhae, M.D. Melb.; Thomas Archibald Malloch, M.D. McGill; Ludlow Murecott Moody, M.B. Lond., L.R.C.P.; Julian Lionel Preston, M.B. Lond., L.R.C.P.; Archibald Cathcart Roxburgh, M.B. Camb., L.R.C.P.; Joseph Wilkie Scott, M.D. Glasg.; Frank Shuffeleotham, M.D. Camb.; Eric Clarence Sparr, M.D. Lond.; Robert Maxwell Trotter, M.D. Aberd.; William Balcombe Winton, M.D. Camb.

Licences to practise physic were granted to 78 candidates who, having conformed to the by-laws and regulations, had passed the required examinations. Diplomas in Public Health were granted, in conjunction with the Royal College of Physicians, to the following candidates who were found by the Examiners to be qualified:—

Lionel Danyers Bailey, L.R.C.P., M.R.C.S., St. George's; Malcolm Barker, L.R.C.P., M.R.C.S., King's College; Cyril Douglas Day, L.M.S.S.A. Lond., Cambridge and St. Bart.'s; Herman Falk (Major, I.M.S.), L.R.C.P., M.R.C.S., M.B., B.C. Cantab., Cambridge and St. Thomas'; Walter Henry Grace, M.B., B.S. Lond., M.R.C.P., M.R.C.S., Guy's; Mervyn John Holmes, M.B., B.S. (Melbourne, Australia), University College; Tam Legge, L.R.C.P., M.R.C.S., University College; Richard Douglas Passey, M.C., M.B., B.S. Lond., Guy's; Eva Louise Cairns Roberts, M.B., Ch.B. Manch., Manchester and King's College; William Leslie Webb, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Guy's; Harold Edward Whittingham, M.B., Ch.B. Glasg., Glasgow and University College; John Pryce Williams, L.R.C.P., M.R.C.S., St. Mary's and King's College.

The following appointments were made, and the newly elected officers gave their faith to the College:—

*Censors.*—Sir Wilmot P. Herringham, Sir Humphry D. Rolleston, Dr. Raymond H. P. Crawford, Sir John Rose Bradford.

*Treasurer.*—Sir Dyce Duckworth.

*Registrar.*—Dr. Joseph Arderne Ormerod.

*Harveian Librarian.*—Dr. T. H. Arnold Chaplin.

*Members of the Library Committee.*—Dr. Hector W. G. Mackenzie, Dr. Dawson Williams, Dr. Arthur Francis Voelcker, Dr. Herbert Ritchie Spencer.

*Curators of the Museum.*—Dr. John Mitchell Bruce, Sir Seymour John Sharkey, Dr. Frederick William Andrewes, Dr. William Hunter.

*Finance Committee.*—Dr. Sidney Philip Phillips, Dr. Arthur Templer Davies, Dr. Herbert Ritchie Spencer.

*Examiners.*—Chemistry: Mr. William Holdsworth Hurlley, Mr. Henry Rondel Le Sueur. Physics: Mr. James Hancock Brinkworth, Mr. Alfred Henry Fison. Practical Pharmacy: Dr. Robert Arthur Young, Dr. David Forsyth, Dr. William Mitchell Stevens, Dr. James Andrew Gunn, Dr. Edward Mellanby. Physiology: Dr. David Henriques de Souza, Mr. John Smyth Macdonald. Anatomy: Dr. Edward Barclay-Smith. Medical Anatomy and Principles and Practice of Medicine: Dr. James Calvert, Dr. William Hunter, Dr. William Aldren Turner, Dr. Horace George Turney, Dr. John Walter Carr, Dr. John Fawcett, Dr. James Stansfield Collier, Dr. Robert Hutchison, Dr. Frederick John Poynton, Dr. Arthur John Hall. Midwifery and Diseases peculiar to Women: Dr. George Francis Blacker, Dr. Henry Russell Andrews, Dr. Hugh J. M. Playfair, Dr. William F. Victor Bonney, Mr. Harold Chapple.

*Public Health.*—Part I.: Mr. John Henry Ryffel. Part II.: Dr. Edward William Hope.

*Tropical Medicine.*—Dr. John C. Grant Ledingham, Dr. John Brian Christopherson.

*Murchison Scholarship.*—Dr. John Fawcett, Dr. Alfred Ernest Russell.

Communications were received from (1) the secretary of the Royal College of Surgeons reporting proceedings of the Council of that College upon May 8th, June 12th, and July 11th last, respectively; (2) Dr. E. A. Gates asking to be allowed to resign temporarily his Diploma of Membership—this was agreed; (3) Lady Allchin offering to the College a portrait of the late Sir William Allchin, by Sir Luke Fildes, R.A.—the thanks of the College were accorded to Lady Allchin. On the recommendation of the Council the Baly medal was awarded to Dr. Leonard Hill, F.R.S. The report of the Imperial Cancer Research Fund was received. Dr. F. W. Andrewes was re-elected a member of the Executive Committee of the Imperial Cancer Research Fund. Sir William Church and Sir Thomas Barlow were reappointed members of the Executive Committee of the Imperial Cancer Research Fund, on the recommendation of the General Committee of the Fund. The President informed the College that the Executive Committee of the Streatfield Scholarship

have awarded the scholarship to Dr. F. G. Cawston, of Durban, Natal. Reports were received from the representative of the College on the General Medical Council and from Sir George Savage on the Chelsea Physic Garden.

*Reports from the Committee of Management of the Conjoint Examining Board.*

The report of the Committee of Management, dated June 3rd last, contained the following recommendations:—

1. The Committee recommend that the following schools be added to the list of institutions recognised by the Board for instruction in Chemistry and Physics—namely, the Central Secondary School, Sheffield, and the Grammar School, Barnstaple.

2. The Committee recommend that the following school be recognised for instruction in Chemistry, Physics, and Biology—namely, St. Paul's School for Girls, West Kensington.

3. The Committee recommend that the following institution, which is already recognised for instruction in Chemistry and Physics, be also recognised for instruction in Biology—namely, Municipal College, Grimsby.

A report of the Committee of Management, dated July 8th, was also received dealing with—

1. The report of the Council of British Ophthalmologists.

2. The substitution of an examination in *Materia Medica* and Pharmacology for the present examination in Practical Pharmacy.

3. The recognition of schools for instruction in Chemistry and Physics.

4. The recognition of the course of instruction in Pharmacology at the University of Cape Town.

5. The report of the Council of the British Ophthalmologists on the teaching and examination of medical students in ophthalmology concludes with the following recommendations:—

(1) No student shall be admitted to the Final Examination qualifying to practise medicine unless he has attended an ophthalmic clinic for not less than six hours a week during a period of three months, and has attended a course of systematic instruction in ophthalmology. (2) No student shall be considered to have passed the qualifying examination unless he has shown a sound knowledge of practical ophthalmology in an examination conducted by ophthalmic surgeons.

In referring this report to the Committee the Council of the Royal College of Surgeons of England also forwarded a resolution stating that in their opinion it is not desirable to institute a special examination in ophthalmology conducted by ophthalmic surgeons. The Committee of Management agree with this resolution, and have therefore considered whether any alteration in the Regulation relating to instruction in ophthalmology is desirable. In connexion with this subject the following resolution, adopted by the General Medical Council on May 31st, 1919, was also considered:—

"That every student should be required to attend a course of practical instruction in ophthalmology of not less than ten weeks' duration, and that no student should be admitted to the Final Examination unless he presents a certificate to the effect that he has attended such a course regularly, and that his work in connexion therewith has reached a satisfactory standard."

The present Regulation of the Conjoint Board, Section II. XXI. 6, requires a certificate—

"Of having attended clinical instruction in ophthalmic surgery in the ophthalmic department of a recognised general hospital, or at an ophthalmic hospital recognised for the purpose by the Examining Board in England, during not less than three months."

The Committee of Management of the Royal College of Physicians of London are of opinion—

That the present Regulation Section II. XXI. 6 covers the resolution of the General Medical Council, and that this Regulation requires a sufficient period of special instruction in ophthalmology; that the provisions of the Regulations Section I., paragraphs VIII. and IX., enable the teachers of ophthalmology in the medical schools and hospitals to hold class examinations and to institute such conditions for attendance on the course as they consider desirable before certificates of attendance are granted by them.

For these reasons the Committee recommend that no alteration be made in the present Regulation relating to instruction and examination in ophthalmology.

2. In the year 1915 the Royal Colleges decided to substitute an "examination in *Materia Medica* and Pharmacology" for the present examination in Practical Pharmacy, but agreed that the new examination should not come into force until January, 1918, and then only if the war be ended. The Committee of Management are of opinion that the time has now arrived when this new examination should be instituted, and they have accordingly adopted the following recommendations to the Royal Colleges, viz.:—

1. That notice be given to the medical schools and by advertisement in the medical journals that an examination in *Materia Medica* and Pharmacology will be substituted for the examination in Practical Pharmacy. 2. That the examination in *Materia Medica* and Pharmacology be taken by all candidates who have not completed the First Examination, including Practical Pharmacy, by May 1st, 1920. 3. That no alteration in the fees payable on the first admission to the First and Second Examinations is necessary. 4. That the fee for re-examination in *Materia Medica* and Pharmacology be 3 guineas. 5. That the capitation fee paid to the examiners be raised from 10s. to 16s. (It is estimated that each examiner will receive at least £40 a year.) 6. That the revised Regulations, with the new synopsis already authorised by the Royal Colleges, be issued.

7. That in addition to the revision in the Regulations already authorised, paragraphs II., III., and IV. of Section III. of the Regulations relating to the conditions of admission to examination of members of English, Scottish, Colonial, Indian, and foreign Universities be modified so as to admit of such students presenting themselves for the Final Examination at the expiration of two years from the date of passing in anatomy and physiology at their Universities, provided the curriculum of professional study has been completed, notwithstanding that the corresponding examination at their Universities in pharmacology and *materia medica* may have been passed in the third or fourth year.

3. The Committee recommend that the following schools be added to the list of institutions recognised by the Board for instruction in chemistry and physics—namely: King's School, Rochester; the Grammar School, Normanton.

4. The Committee recommend that the course of instruction in pharmacology and practical pharmacology in the Medical Department of the University of Cape Town be recognised by the Board.

## The Services.

### ARMY MEDICAL SERVICE.

Major-General Sir Menus W. O'Keefe, K.C.M.G., C.B., retires on retired pay.

Major-General Sir M. P. C. Holt, K.C.B., K.C.M.G., D.S.O., is appointed Honorary Surgeon to the King, vice Major-General (temp. Lieut.-General) Sir W. Babbie, V.C., K.C.M.G., C.B., K.H.S.

### ROYAL ARMY MEDICAL CORPS.

Lieut.-Cols. L. F. F. Winslow and R. C. Lewis retire on retired pay.

Major and Bt. Lieut.-Col. C. R. Sylvester-Bradley and Capt. A. C. Hammond-Searle relinquish the acting rank of Lieutenant-Colonel on re-posting.

Major A. E. Smithson is placed on retired pay.

Captains to be Majors: A. W. Howlett, G. F. Dawson, H. S. Dickson, W. A. Spong, H. P. Hart, J. C. L. Hingston, A. Hendry, R. E. Todd, G. Petit, and W. R. O'Farrell; (acting Majors) J. A. Renshaw, D. B. McGrigor, R. F. O'T. Dickinson, A. E. B. Jones, J. R. Lloyd, J. F. Grant, and C. Kelly; (acting Lieut.-Cols.) R. G. S. Gregg and B. A. Odum; (Bt. Major) F. T. Dowling.

Temporary Captains relinquishing the acting rank of Major: R. S. Dickie (on re-posting), T. E. R. Branch.

Capt. D. Forsyth Panton, from Special Reserve, to be Lieutenant and to be Temporary Captain.

Temp. Capt. A. E. S. Pringle-Pattison to be Captain.

Capt. H. G. Trayer resigns his commission.

Officers relinquishing their commissions:—Temp. Lieut.-Col. H. L. Eason retains rank of Lieutenant-Colonel. Temporary Majors retaining the rank of Major: C. S. Read, J. Phillips, T. M. Frood, W. H. Thompson. Temporary Captains granted rank of Major: A. T. Edwards, A. C. S. Courts, W. H. Welsh, J. A. Doull, J. S. Stewart, A. C. Bryson. Temporary Captains retaining rank of Captain: G. S. Banks, J. V. Grant, J. W. N. Roberts, V. T. P. Webster, H. M. Brown, J. F. Smith, A. S. Richmond, P. A. B. Clark, S. F. Cheesman, J. H. Glover, J. M. Johnstone, W. G. Fee, R. W. T. Clappett, L. W. Batten, H. F. Brice-Smith, F. P. Hearder, G. Robinson, A. C. Profitt, T. L. Butler, M. W. Shutte, J. B. Lester, A. G. Payne, J. F. Sheppard, W. H. W. C. Carden, D. A. Farquharson. Temporary Lieutenants retaining the rank of Lieutenant: W. P. McCowan, W. A. S. Magrath, W. E. Martin, R. R. MacGregor, H. E. Thompson.

### SPECIAL RESERVE OF OFFICERS.

The undermentioned Captains to be acting Majors whilst specially employed: M. Stewart, R. D. Cameron.

### TERRITORIAL FORCE.

Lieut.-Col. Sir Willmot P. Herringham is retired on attaining the age limit, and is granted the honorary rank of Major-General.

Capt. (acting Lieut.-Col.) G. R. Rickett, relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Cpts. (acting Majors) W. Scott, A. E. Mackenzie, and L. M. V. Mitchell relinquish the acting rank of Major on ceasing to be specially employed.

1st Eastern General Hospital: Cpts. (acting Majors) G. S. Haynes and J. C. W. Graham relinquish the acting rank of Major on ceasing to be specially employed.

3rd Northern General Hospital: Major H. R. Dean is restored to the establishment.

### TERRITORIAL FORCE RESERVE.

Capt. Sir James P. Stewart, from 4th London General Hospital, to be Colonel.

Capt. M. W. K. Bird relinquishes his commission on account of ill-health contracted on active service, and retains the rank of Captain.

### ROYAL AIR FORCE.

Medical Branch.—Major A. Fairley (Surgeon Lieut.-Comdr., R.N.) relinquishes his commission on ceasing to be employed.

The undermentioned are transferred to unemployed list: Lieut.-Col. T. Philp; Cpts. J. Freeman, C. C. O'Malley, (Hon. Major) D. Wilson, A. Sutcliffe, J. L. Whatley, H. M. Holt; Lieut. A. J. Swanton.

### DEATHS IN THE SERVICES.

Captain George Thomas Whyte, F.R.C.S. (Irel.), D.P.H., R.A.M.C., who died at the Military Hospital, Spike Island, Queenstown, on June 9th, qualified in 1892 and took the F.R.C.S. (Irel.) in 1901. He served as civil medical officer to the Field Force during the South African War, and after obtaining a public health diploma returned to his post on the West African Medical Staff in Northern Nigeria. He had served 18 months in France during the war that is past, and died after a brief illness of four days. He leaves a widow and a little girl, aged 2 years.

"Audī alteram partem."

### THE PENSIONS PROBLEM.

To the Editor of THE LANCET.

SIR,—In connexion with the assessment of the pensions to be allotted to partially disabled officers and men, the power of prognosis of the medical profession is in many cases being submitted to a test that it cannot sustain. It is possible to estimate with some measure of accuracy the degree of future disability of a man who after an injury has had a limb or portion of a limb amputated. For these and some other similar cases a partial pension can be more or less fairly assessed. It is quite impossible to forecast with any approach to certainty the future average employability and proportionate earning capacity of a man who has sustained a gunshot wound of a viscus or has suffered from tuberculous or malarial infection. For these and very many similar cases no fair individual assessment can be made. Such cases could be put in groups according to their history and present condition, and a rough calculation made as to the average incidence of future disability amongst all the members in each group; just in the manner in which impaired lives seeking life insurance are dealt with. Probably something of this sort is being done now in allotting partial pensions. But what will be the result? Those with partial pensions who do not subsequently break down will be heard of no more, but the minority who, according to the law of averages, will break down badly will find their small pensions altogether inadequate, their hardships will quite rightly come under public notice, and the profession will be blamed for not having made for them adequate provision.

It would be well, therefore, for the profession at once to make clear to the public that it is quite impossible for science to provide the data on which a fair pension can be assessed in the case of large numbers of partially disabled men. Since, however, the number of such men—some not yet demobilised, others demobilised but still on temporary pensions—is very great, some provision must be made to meet their special risk of disability. For a considerable number of cases the most suitable way of meeting the risk would be the issue of a sickness insurance policy guaranteeing in the event of a breakdown in the future the periodical payment by the Government of a sum to meet the then ascertained degree of disability so far as it is not met by any other national insurance. In some cases such a policy would take the place of a partial pension, in others it would be additional to it. The task of dealing with many cases, which now present an insoluble problem, would at once become simple. It would only be necessary at the outset to earmark certain cases as having been rendered by injury or disease resulting from war service specially liable to relapses of disability, and later on to determine the fact of disability should it occur. The Ministry of Pensions must naturally look to the medical profession for advice as to fair and proper ways of dealing with all the various types of cases amongst those whose health has suffered from war service. Those medical men who are in a position to offer such advice should lose no time in pointing out that there is a large proportion of cases whose special claim upon the nation cannot be met by the old-fashioned method of a pension assessed according to the demonstrable degree of disability, but can be quite satisfactorily dealt with by a well-considered scheme of sickness insurance. Such a scheme could be easily devised and at once put in force. Those who ought to come under it are, as things stand at present, either not having their claims met or are being dealt with in a manner which will ultimately prove unfair to them or to the State.

I am, Sir, yours faithfully,

August 4th, 1919.

LAURISTON E. SHAW.

### INCIPIENT MENTAL DISEASES.

To the Editor of THE LANCET.

SIR,—In your issue of July 26th is published a letter by Dr. L. A. Weatherly on the treatment of cases of incipient mental disease, and while fully agreeing with most of his statements I do not think too strong a protest should be made against the proposed limitation of sojourn for such

cases to six months. I quite agree with Dr. Weatherly that under such a regulation a certain number of patients may be found nearly well at the time they have to leave the institution; but I would rather this happen than have in any way retarded the facilities for early treatment that are apparently rapidly materialising.

In dealing with many thousands of cases of acute mental disorder in the early stages during the war in a military hospital I found that three months was an average period of residence. Out of 1000 cases in hospital at the end of a two years' period of admissions only 200 were found to have been resident six months or over, and 70 per cent. of these were looked upon as unlikely to make an early recovery. At the time I refer to it was the custom to keep such cases for nine months prior to certification, but from my previous experience I consider that any retention of chronic cases in a hospital intended for treatment of early cases is to be condemned in the strongest possible terms.

An atmosphere of cure is what is wanted above all things in such an institution, and for this reason I would support the limitation to six months, but would suggest that the words "provided that the patient is not making obvious improvement" be added, as a means of overcoming the difficulty referred to.—I am, Sir, yours faithfully,

RICHARD EAGER, M.D.

Devon Mental Hospital, Exminster, July 30th, 1919.

### THE COÖRDINATION OF CLINICAL RESEARCH AND PSYCHOLOGICAL MEDICINE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of August 2nd there appeared an article by Dr. Bedford Pierce on "Psychiatry a Hundred Years Ago," also a letter from Dr. E. Goodall setting out what Cardiff is about to do in the present. I should like to draw attention to the fact that Birmingham already has a special hospital for the treatment of nervous diseases, the largest department of which is a "psychoneurosis clinic." The hospital was founded in 1913, but before beds could be provided in a suitable, quiet locality the war broke out. The governors, therefore, deemed it wise to postpone the opening of the in-patient department for mental cases until after the war. Immediately upon the cessation of hostilities they acquired a very suitable property with large grounds attached, and this will be ready for the reception of patients by the end of next month.

I wish to emphasise, in this connexion, two or three points which seem to me to have been passed over by the writers referred to above. The first point—mentioned in your leading article but not sufficiently stressed—is the necessity of separating early borderline and psychogenic from certifiable cases. If the public even suspect that they or their friends are being invited to attend an institution in any way associated with an asylum the early cases, in which treatment is most likely to be effectual, will not present themselves. For this reason it seems to me essential that the special clinics now springing up should be kept free from any taint of the asylum. The term "hospital for nervous diseases" or disorders seems acceptable to the general public, and I suggest that its adoption would avoid the danger under discussion. There is another advantage to be gained by working the new clinics from a special hospital for "nervous diseases"—viz., the well-recognised fact that even in cases in which the primary causal factor is indisputable of organic origin, it is nevertheless the super-added functional or psychogenic symptoms which cause most trouble, though they are also the most amenable to suitable treatment. Such cases willingly attend a hospital for nervous diseases where both elements of their trouble can be tackled, but they would merely be offended were they asked to attend a psychiatric clinic. Again, although borderline and psychogenic cases should be separated from advanced and hopeless cases of insanity, it will, from the research point of view, be a great advance if all diseases with a pronounced psychogenic element can be grouped and observed together with ordinary neurological cases instead of being dealt with by the more or less logic-tight-compartment methods hitherto in vogue.

My last point concerns the desirability, in large towns at any rate, of separating the out- from the in-patient department. The former must be in a central situation, which implies a small and noisy site, whereas the latter ought to

be in a quiet locality and have large grounds and workshops attached, so that occupation and recreation may be available for the patients. During the year 1918 the outpatient attendances at the Birmingham Nerve Hospital totalled 17,246, while the beds provided at present are for 30 patients only. It would be unwise to attempt to divert so many out-patients from a conveniently situated central institution, and impracticable to provide adequate accommodation for this special type of in-patient upon a centrally situated site. The governors, therefore, have located their new in-patient department for functional and borderline cases at some distance from the original institution, although this involves an increase in the expenses of management.

My plea, then, is that the basis of the new clinics be broadened and that at the same time everything reasonable be done to secure the confidence of those whom we are seeking to benefit.—I am, Sir, yours faithfully,

ALFRED CARVER.

Birmingham and Midland Hospital for Diseases of the Nervous System, Birmingham, August 4th, 1919.

## THE ORIGIN OF LIFE: THE WORK OF THE LATE CHARLTON BASTIAN.

To the Editor of THE LANCET.

MONSIEUR,—Je n'aurais eu, pour le moment, que peu de chose à ajouter à ma lettre parue dans vos colonnes le 28 Juin dernier, si l'intervention de M. John Butler Burke (THE LANCET, 26 Juillet) n'était venue introduire de nouvelles hypothèses dans l'interprétation des expériences du Dr. Bastian et autres essais du même genre. Je dois pleinement reconnaître le très grand intérêt des *Radiobes* de M. Burke, dont les propriétés biotiques sont saisissantes; mais Raphaël Dubois (avant M. Burke) et Martin Kuckuck (après lui), ont obtenu des résultats exactement semblables en utilisant des sels non radioactifs de baryum, strontium, &c. Comme les radiobes de M. Burke, les *microbioides* de Dubois et les *baryumaytoden* de Kuckuck grossissent, se meuvent, se reproduisent par bipartition, semblent parfois se conjuguer à la manière de certaines algues monocellulaires: ce qui ne les empêche nullement de passer, en vieillissant, à l'état de cristaux polyédriques inertes. Il semble difficile de voir dans ces corpuscules autre chose que de très petits cristaux imparfaits dont le stade précristallin se trouve considérablement prolongé par l'ambiance colloïdale; d'ailleurs, tous les cristaux en voie de formation, surtout dans des milieux très visqueux, se comportent temporairement, au point de vue structural et dynamique, comme des êtres vivants. A l'appui de ce que j'avance, je mentionnerai les *Protobies* de A. L. Herrera (cristaux imparfaits en milieux siliciques) et nos propres expériences sur la formation des cristaux.<sup>1</sup> La radioactivité me semble, en toute sincérité absolument étrangère à de telles questions. Quant au rôle de la diffusion et de la pression osmotique dans l'apparition des bactéries minérales de Bastian et Mary, il doit être inexistant. Sans doute, mon éminent ami Stéphane Lednc a produit, par osmose, et aussi par diffusion de cristalloïdes dans les gels colloïdaux, une profusion de formes et de structures artificielles de nature à nous renseigner sur l'intervention des forces capillaires dans la détermination des caractères morphologiques et physiologiques généraux des organismes. Mais les croissances osmotiques, que nous avons aussi étudiées depuis 1908, sont des vésicules, et les figures de diffusion dans les gels n'ont pas d'existence en-dehors de leur substratum colloïdal. Les corpuscules synthétiques de Bastian sont formés par les colloïdes eux-mêmes, et ne sont pas vésiculaires. Pour expliquer le mécanisme physique de leur développement, c'est exclusivement à la physico-chimie colloïdale qu'il faut faire appel, et tout l'intérêt du problème tient précisément à ce fait qu'il n'y a qu'une physico-chimie colloïdale, embrassant dans des lois communes l'organique et le minéral.—Je suis, Monsieur, très sincèrement vôtre,

ALBERT MARY.

Institut de Biophysique, Paris, 30 Juillet, 1919.

To the Editor of THE LANCET.

SIR,—Mr. S. G. Paine, writing some time ago in your columns on the "Origin of Life," in particular connexion with the work of Charlton Bastian, mentioned that the sand of the Egyptian desert, which is subjected to a considerable heat, contains living protozoa. I do not know what temperature

these organisms can withstand, but it should be remembered that under those conditions the heat will be dry. The following facts, however, show that the limits of resistance of certain organisms, even to moist heat, are greater than was suspected. M. Paul Portier, professeur à l'Institut Océanographique, in his recent work entitled "Les Symbiotes" (Masson et Cie, 1918), describes certain symbiotic micro-organisms, isolated from both vertebrates and insects, which are extraordinarily resistant to physical and chemical agents. When freshly isolated they are killed by a temperature of 100° C., but after a few subcultivations the temperature must be raised to 115° C., moist heat. In a dry atmosphere they can resist a temperature of 140° C., and are only just killed by a temperature of 150° C., maintained for half an hour. Further, these organisms may be boiled in absolute alcohol, chloroform, or acetone, and yet remain capable of cultivation. In one set of experiments, indeed, they withstood heating in acetone in sealed tubes at a temperature of 100° C. to 120° C.

In connexion with this subject it may be mentioned that certain enzymes, as, for instance, ptyalin, which begin to decompose at a temperature of 60° C. and are completely destroyed by temperatures of less than 100° C., can, when dialysed free from all traces of electrolytes, be boiled without losing all activity, which returns on the readdition of a little salt. In view of such facts, experiments similar to Dr. Bastian's must be carried out with the greatest possible precautions as to technique and sterilisation. It is true that the interesting experiments of Dr. Mary were carried out at a temperature which should kill any organisms at present known. Dr. Mary, however, admits that the bodies found in his solutions do not contain any protein and are incapable of cultivation, even on the simple solutions which are supposed to generate them—that is to say, they are not living matter in any ordinarily accepted use of that term.

Since writing the above, I have seen Commander Bastian's letter of July 26th. I gather the objections he raises to my experiments<sup>1</sup> are two. (a) That the "yellow solution" contained ammonium phosphate and phosphoric acid in addition to the proper ingredients, and (b) that the tubes were kept for too long a period, during which the "organisms," which were supposed to have developed, died. In the first place, I must thank Commander Bastian for pointing out my error. I cannot excuse such carelessness, my only explanation is that when writing up the account of the experiments during the war and several years after the solutions were made up, I foolishly referred to Dr. Bastian's "Origin of Life," instead of to my own notes, in order to ascertain the composition of the solutions, which being quite arbitrary, I had not unnaturally forgotten. Though there is no doubt as to Dr. Bastian's meaning when carefully read, anyone who will take the trouble to look up the reference (p. 30) will see that the words, "the proportion of the other ingredients remaining always the same," might be misleading in the hurry of the moment. I have now looked up my original notes, and I beg leave to correct the error by making the following quotation from my note-book:—

"On Sunday, August 10th (1913) ..... test-tubes of hard white German glass 5 in. × 3/4 in. .... were charged half full with Dr. Bastian's 'yellow solution,' consisting of 8 drops of liquor ferri penitricis and 3 drops of dilute sodium silicate (from A and H's sample reserved for Dr. Bastian) to each oz. of distilled water, ..... these proportions gave the port-wine colour recommended by Dr. Bastian with a minimum amount of sediment."

On the next page the correct formulae for both solutions are written in a tabular form above the two series of tubes. I trust that Commander Bastian will accept this evidence. With regard to his second criticism, I think Commander Bastian makes a misrepresentation. He implies that the tubes of the "white solution" were kept for 38 months before being opened, whereas the truth is that the tubes of both series were opened at varying periods from 1½ months to 38 months (at intervals of about 3 months): The period of 38 months was only the maximum duration of the experiment. I believe the longest that Dr. Bastian kept his tubes was two years. When planning the experiments I therefore considered that if I kept some of the tubes for three years I could not be accused of impatience. I must apologise for taking up so much of your valuable space, and beg to remain,

Yours faithfully,

The Biochemical Laboratory, Cambridge,  
August 2nd, 1919.

H. ONSLOW.

# A CRITICISM OF THE MEMORANDUM ON MALARIA.

To the Editor of THE LANCET.

SIR,—I must protest against the pernicious and dangerous advice given by Dr. Gordon Ward in his criticism of the Memorandum on Malaria in your issue of July 19th. He says:—

"The most important principle in the treatment of malaria in pensioners is the improvement of the natural resistance of the body with the aid of as little quinine as possible."

It is just such treatment that is filling the wards in our hospitals with pensioners and demobilised men. They all come in with the same story. Since they left the Army they have had recurrent attacks of fever, been treated by civil practitioners with totally inadequate doses of quinine, which have had no effect on their malaria, and finally have to come into hospital. There they are put on 10-gr. doses of quinine sulphate in solution, three times a day, and they very rarely have more than one rigor after the treatment has begun. It is a great relief to the men to find they are rid of their fever in 48 hours, after recurrent attacks; in one case for five weeks on minimum doses of quinine. It may now be regarded as established beyond a doubt that the optimum dose of quinine during the attack is that stated in the Memorandum—viz., 10 gr. of sulphate or hydrochloride in solution three times a day; whilst the experience at concentration centres has proved that 10 gr. a day is a valuable anti-relapse precaution. If this be carried out regularly over a prolonged period, say, three months, and relapses prevented, the natural resistance of the body will assert itself and justify Osler's dictum, that the proper treatment of malaria is "quinine and time, both in divided doses."

The danger we have to fight against is the fear of the civil practitioner to give adequate doses for a sufficiently long period, and we are not helped by such advice as Dr. Ward gives. Dr. Ward's picture of the man with chronic tachycardia and effort syndrome is in most cases the result of inadequate doses of quinine for a short period, allowing frequent relapses and general deterioration of health. If Dr. Ward will re-read the Memorandum carefully he will find that the intramuscular method of administration is recommended only when vomiting is so persistent that quinine cannot be given by the mouth, or in pernicious attacks, when no time must be lost. It is not advocated in simple attacks without complications.

Twenty months in the malaria section of a military hospital in England have only confirmed what 20 years' experience in the tropics had already taught me, that the intramuscular giving of quinine is a most valuable method in urgent cases, and that by using quinine bi-hydrochloride, being careful about sterilising the solution, and all the apparatus, and making the injection actually into the muscle and not subcutaneously, the risk of causing abscess is small, whilst a very elementary knowledge of anatomy will enable one not to inject in the close proximity of an important nerve trunk. In about 2000 cases I have had through my hands in this country I have seen only one partially paralysed arm as the result of an injection, and in that case the needle had been inserted directly over the musculo-spiral nerve. Pernicious attacks in this country fortunately are rare, but in such cases the intramuscular route is pre-eminently the safest for the civil practitioner to follow.

I am, Sir, yours faithfully,

T. H. JAMESON, M.D., M.R.C.P. Edin.,

London, July 31st, 1919. D.T.M.H., D.P.H.

## DUPLICATION IN HUMAN SPERMATOOZOA.

To the Editor of THE LANCET.

SIR,—If Mr. S. R. Tattersall, who communicated to THE LANCET of August 2nd on the above subject, would look up Broman's "Normale und Abnorme Entwicklung des Menschen," p. 18 et seq., he will find the conditions he has described as well as excellent photographs of the specimens. He will further find an interesting discussion of the whole question of abnormal spermatozoa, by one who has done much work on the subject, but whose magnificent book seems to be little known.

I am, Sir, yours faithfully,

EDWARD FAWCETT,

August 2nd, 1919. Professor of Anatomy, University of Bristol.

## THE RESULTS OF COMPLETE COLECTOMY.

To the Editor of THE LANCET.

SIR,—Major James Taylor is quite correct in stating, in your issue of August 2nd, that there is a very general belief that many patients do not recover from the operation (of complete colectomy), and that those who do are no longer capable of leading an active life. This general impression is not likely to be changed in any way by a perusal of Major Taylor's paper. His small series of cases is of undoubted interest, but it is to be regretted that he does not give any information of the after-progress of Cases 1 and 2 and a full description of the "diseased condition of the rectum" held responsible for the imperfect recovery of Case 3. The operation of complete colectomy for intestinal stasis will remain under a cloud so long as those surgeons who perform it are content to support their views by the publication of their cases in this imperfect manner.

I am, Sir, yours faithfully,

Leeds, August 2nd, 1919.

J. F. DOBSON.

## SHELL SHOCK IN FISHES.

To the Editor of THE LANCET.

SIR,—Dr. Alfred Carver narrates in your columns last week certain experiments on fishes; these were made only on perches. Dr. Carver will be interested to hear that Dr. A. G. Mayer<sup>1</sup> found that when a half stick of dynamite was exploded within 3 ft. of a small shark (Carver's zone A with a vengeance) no apparent injury was produced; the same thing applied in a lesser degree to such teleosts as lack swim-bladders. When swim-bladder fishes were killed by the explosion their swim-bladder burst, the tissues were crushed, and the vertebral column was often broken. Mayer attributes the injurious effects of explosives in fishes, when present, to mechanical laceration of tissues, and especially the crushing inward of air-filled cavities. A full abstract of Mayer's paper appears over my signature in the *Review of Neurology and Psychiatry*, 1917, xv., p. 335.

I am, Sir, yours faithfully,

London, N.W., August 1st, 1919.

LEONARD J. KIDD.

## HOME HOSPITAL ESTABLISHMENTS AND THE WAR MEDALS.

To the Editor of THE LANCET.

SIR,—I wish to call attention to the gross unfairness of laying down a geographical qualification for the 1914-15 Star, General Service, and Victory Medals, at all events as regards the medical establishments. Elderly medical men in the R.A.M.C., whether Reserve, Special Reserve, or Territorial, were called up at the outbreak of the war in August, 1914. Often this entailed the abandonment of our private practices, our means of livelihood, and serious financial loss. We have been in charge of, or performing important services in, large general hospitals and their auxiliaries, or in the military hospitals and training camps; and we have been kept in this country because we could not be replaced. We have been overwhelmed with work which has been absolutely essential, yet we have not been considered to be entitled to the medals issued to commemorate this, the greatest of all wars, because, forsooth, we have not crossed the Channel!

This decision is contrary to precedent. It has always previously been recognised that the medical establishment had a special claim to medals issued to commemorate a campaign in view of their special work of dealing with the wounded. The hospitals in this country have equally with those in France been associated with the fighting forces. They have taken wounded practically direct from the battlefields, Americans, Belgians, Chinese, French, Serbians, besides the British and Dominion troops; yet, having performed these services to our Allies, we alone of all the Allied forces are not to have the Allies Medal! It is sought to justify this discrimination by excluding this country from the list of "war areas." But we who, by the exigencies of the service, were retained here, have been declared to be serving "on Active Service" and have drawn "Field Allowances." Hitherto the necessary corollary to such conditions has been the issue of the medal granted for the campaign.

What makes this discrimination more remarkable is that it does not apply to Dominion troops. They receive not

<sup>1</sup> Proc. National Acad. Sciences of U.S.A., 1917, iii., p. 597.

only the war medals, but also the chevrons, without the necessity of crossing the Channel. Hence, in their case, it follows that they are given, not according to the precise locality in which the war service was rendered, but merely from the place of residence before the war. Surely a "reductio ad absurdum." Another precedent for the issue of a war medal without actually entering a "war area" was the issue of the South African Medal, without clasps, to the Militia Garrisons in the Mediterranean.

It is suggested that hospital and medical services rendered in this country should be recognised by the issue of the General Service Medal, without the clasps, which will, no doubt, later be granted for service in particular battles or war areas; and that the Victory Medal should be given with late clasps. Any other distribution is most unfair to those who have formed the personnel of the hospitals and medical establishments in this country. The Royal Red Cross has been given to a small percentage of the nursing staffs, and no one has ventured to deny the justice of the award; but hospitals are not run by nurses alone. With the exception of a few commandants, the V.A.D. workers have been ignored.

Practically all of us are now returning to civil life, with absolutely nothing to indicate that our services have been appreciated, or that we have done our duty in accordance with the orders of the higher authorities; but I am confident that I speak for my medical colleagues when I say that we desire no decorations which are not shared by the whole male and female personnel who have so nobly sacrificed themselves to tend and succour the sick and wounded in the hospitals of this country, services which have been absolutely indispensable to the victory of the Allies, and which are universally recognised as reflecting the utmost credit and honour upon all concerned.

I am, Sir, yours faithfully,

August 5th, 1919.

IGNORED.

## THE MARRIAGE OF ASSISTANT MEDICAL OFFICERS AT ASYLUMS.

To the Editor of THE LANCET

SIR,—I read with great interest in THE LANCET of July 19th the article setting forth the new conditions laid down for assistant medical officers in the London County Asylums. In the issue for July 26th there is an advertisement for an assistant medical officer at a borough asylum, and it may interest you to know how the vacancy has arisen. In April, 1907, I became assistant medical officer at a borough asylum, and continued to hold that post till I joined up in July, 1917; but I still remained technically assistant medical officer, and my post was open for me when I left the Army. In February of this year I married, and shortly after was asked by my committee to resign; this I refused to do, as I had not done anything wrong. They then gave me notice of dismissal on the ground that there was no accommodation for a married A.M.O. I replied to that by saying that I did not ask for extra accommodation, and that I was willing to go back and live as a single man as I did previously, my wife living elsewhere. Their reply was simply to dismiss me because I had married.

It is surely cruel and unjust to penalise marriage so very heavily, and to dismiss a man—after ten years' service—just because he has married. The committee expressed themselves as being quite satisfied with my services, and alleged no reason for dismissing me but the fact that I have married. I have been turned out of my post, at 45 years of age, without pension or compensation of any kind, and with practically no chance, by reason of age, of getting another asylum post, the work to which I devoted all my professional life. I am still serving in the Army, so the action of the committee is at least premature. I think such action by a committee ought to be made widely known, and I shall be glad to hear the views of others.

I am, Sir, yours faithfully,

July 30th, 1919.

DISMISSED.

THE Committee of the Territorial Force Medical Officers' Association are making arrangements for a dinner on October next for Territorial medical officers. Any medical officer who wishes to be present should send his name to Lieutenant-Colonel D. L. Hamilton, R.A.M.C., T.F.R., 7, Russell-square, London, W.C., who is acting as honorary secretary for the dinner.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### PENSIONS REORGANISATION.

##### Changes in Medical Arrangements.—Increases in Personnel.

THE House of Commons went into Committee of Supply on Thursday, July 31st, on the Supplementary Vote of £45,855,000 for the salaries and expenses of the Ministry of Pensions.

Sir L. WORTHINGTON-EVANS (Minister of Pensions) stated that the decisions of the Government upon the recommendations made in the interim report of the Select Committee on Pensions would call for an extra expenditure for the remainder of this year of about £11,000,000, so that the estimates should be treated as £86,000,000, and not as just under £73,000,000 as presented. For a full year, as long as the number of pensioners remained at or near the maximum, the rate would be about £96,000,000. Dealing with the new scheme of decentralisation, the right honourable gentleman said that all medical boards and arrangements for medical treatment would be dealt with by the regional medical officer. Proceeding to speak of the medical services of the Ministry, the Minister said:—

"I have been fortunate in securing as Chief Medical Officer Colonel Webb. During the war he held an important position in the medical service of the War Office, and he brings a very special knowledge of the requirements of the serving man who is now a pensioner to the service of the pensioners. The work of this division is probably the most important of any of the divisions of the Ministry. It deals with that primary necessity of the disabled man—namely, the provision of medical treatment both in hospitals and clinics and convalescent centres. When the bulk of the men were in the Army, the Army did the work, but demobilisation has transferred the necessity for providing hospitals and clinics from the War Office to the Ministry of Pensions. We have already taken over from the War Office two hospitals, and arrangements are practically complete for the transfer of others. The Red Cross are assisting the Pensions Ministry as they assisted the War Office.

#### Nursing Service.

"As we take over hospitals we are bound to provide a nursing service, and I am glad to say that Queen Alexandra has graciously consented to be president of the Pensions Nursing Service. I have been fortunate to secure as matron-in-chief Miss M. E. Davies, R.R.C., who will be assisted by an advisory committee. I am also hoping to have ready very shortly certain convalescent centres at Blackpool, Epsom, and elsewhere, in which men who, while suffering from disabilities which require more or less prolonged out-patient treatment, will be able to employ their time to their own advantage by receiving preliminary training to fit them for their after-life. I have been impressed by the large number of out-patients attending hospitals for perhaps half an hour a day, upon whose hands time hangs heavily. I believe that if such men as these are admitted to convalescent centres they will, while receiving treatment, be capable of much useful training during their convalescent stage, and more rapidly benefit by the industrial training thereafter given them under the Ministry of Labour. Moreover, experience shows that many men, attracted no doubt by the high wages and the demand for labour during the latter stages of the war, who went into industrial life, are likely to break down and require more or less prolonged convalescent treatment. For these, also, the convalescent centres are likely to prove of great use.

#### Medical Boards.

"Until recently the boarding of the men applying for pensions and the re-boarding of men on renewal of pensions was performed by the Ministry of National Service, but on April 1st last the central and regional staff of the Ministry of National Service was transferred to the Ministry of Pensions, and we became directly responsible for the boarding of all men. On August 4th we are taking over from the War Office the Re-survey Boarding of Officers. To give the Committee some idea of the extent of the increase of the work of medical boards, I may inform them that 229,697 men were examined by medical boards in the six months ending June last. There has been a steady and rapid increase in the number of men boarded owing to demobilisation, and in June last 45,000 men were boarded.

#### Medical Appeal Boards.

"The Committee may be aware that under the system hitherto prevailing the medical officers at the headquarters of the Ministry reviewed the decisions of these boards and a medical officer was authorised to alter the amount of a man's assessment by a board without himself re-examining the man. Many complaints of this system have been brought to my

notice, and the Select Committee has recently called special attention to this system, and has recommended that any case of doubt should be sent for re-hearing by the same or by a second board, who in every case should examine the man in person. I entirely agree with this recommendation. Indeed, I informed the Select Committee when I gave evidence before it, that I intended to alter the system as soon as the decentralised regions were set up. While it was probably impossible to arrange for Appeal Boards before the Ministry of Pensions had its own medical personnel available to sit on boards and specialists, both surgical and medical, at its hospitals and clinics to constitute the boards, it will be possible to set up the Appeal Boards as soon as the medical personnel in the regions has been completed. Thereafter, a definite procedure will be laid down, which will be followed in all cases—namely, that if the Medical Assessor, on scrutinising the report of the board, is not satisfied that substantial justice has been done either to the pensioner or to the taxpayer, he is not to alter the assessment, but he is to refer the case either to the same board or to an Appeal Medical Board for a re-examination of the man—and similarly, if the pensioner himself is not satisfied that his degree of disability has been correctly assessed—that is to say, if he is not satisfied with the amount of his pension, he will have the right to appeal himself to a Medical Appeal Board, whose decision in the case has to be treated as final, subject to this proviso, which is in the man's interest, that if he gets seriously worse during the period for which the assessment has been made, he may go to a medical referee who may give him temporarily a higher allowance pending the reconsideration of his case by the board. This arrangement of Appeal Boards, while, I believe, absolutely necessary in the interests of justice and to give the pensioner a reasonable assurance that his case is properly considered, will entail a large increase in the medical personnel, which can only be supplied if not only the permanent medical staff of the region is available for boards, but also the specialists attached to the hospitals and clinics, and probably in some cases the medical referees.

#### *Artificial Limbs.*

"As regards the provision of artificial limbs, soon after I became Minister I wanted to be satisfied that the provision of artificial limbs for both officers and men was sufficient, and that the best limbs were being supplied. I accordingly set up a very strong Committee, upon which several Members of the House kindly served, and they have recently reported. On the whole their report shows that the position is satisfactory. They have made several recommendations which are in the course of being carried out. Perhaps the most important is that an expert Committee should be set up to review all the various forms of artificial limbs at present made with a view to standardisation, by selecting the best from each limb. It is proposed that fitting centres shall be established in connexion with orthopaedic hospitals spread throughout the country, and that in addition repair depôts shall be opened in populous centres, so that minor repairs can be made in a short time. I have also referred to the Committee the extent to which fibre pylons should be supplied and used by men with artificial limbs. I fancy that fibre pylons will take their place alongside artificial limbs much as a slipper does to a boot, and that a man with an artificial limb coming home from his daily occupation will be glad to change it for a light fibre pylon. However, that is primarily a surgical question, and I have therefore referred it to the surgeons for advice.

#### *Tuberculosis.*

"I was also not satisfied that the provision made for the pensioner suffering from tuberculosis was sufficient, and in agreement with the Minister of Health we appointed a Joint Committee for the purpose of thoroughly investigating this question. The Joint Committee has now reported, and immediate consideration will be given to the report.

#### *Independent Tribunals.*

"The Government is prepared to accept the recommendation of the Select Committee that the appeal tribunals shall be set up under an authority independent of the Ministry of Pensions, and a Bill will be introduced as soon as possible to empower the Lord Chancellor to set up appeal tribunals and to make the necessary regulations in respect to the procedure. The tribunals will consist of one legal representative, either a barrister or solicitor, who will be chairman of the tribunal, and a disabled officer in officers' cases and a disabled man in men's cases with a duly qualified medical practitioner. Any refusal on the part of the Ministry to a claim for pension on the ground that the disability is not attributable to, or aggravated by, military service, or is due to serious negligence or misconduct of the claimant, will be subject to appeal by the claimant to this independent tribunal. Similarly, a widow or a motherless child whose claim to pension is rejected on the ground that the death of the officer or man was not due to military

service will be subject to appeal. In this way there will be granted a statutory right to assert a claim to pension and a statutory court, independent entirely of the Ministry, will be the sole and final judge of whether the right exists in a particular case.

#### *Appeals on Amount of Pension.*

"It is suggested by the Select Committee that there should be a lay ex-service element on the tribunal, but as the assessment questions are mainly medical questions the medical element should have a majority, and they advise that this medical element should comprise senior surgeons and specialists in the diseases or injuries causing the disabilities under consideration. This recommendation appears to me to be entirely impracticable. During the last six months 920,439 awards have been made, or, if I deduct from this total awards to widows, children, and dependents, nearly 700,000 awards have been made either for the first time or on renewal to men. These awards are made for varying periods for from six to 12 months. The Select Committee recognises that an appeal would be of no use unless the medical men upon the appeal tribunal were more authoritative than the medical men who made the original assessment. If even 1 in 10 men appealed we should have something like 70,000 appeals in six months, and the delays would be so great that the appeals could not be heard before the pension had expired. Moreover, it would be impossible to get the authoritative consultants and specialists in sufficient numbers to form the appeal tribunals. I do not believe that a reform is possible upon these lines. I do, however, agree that it is quite wrong for any medical assessor who has not seen a man to alter an assessment made by a board who has seen the man, and as soon as the regional organisation is complete Medical Appeal Boards will be set up to which either the man or the department can appeal in the event of the assessment being challenged. I ask the Committee to believe me that this is the practical way of curing the evil which the Select Committee has pointed out. Any outside tribunal dealing with these assessments would cause so much delay as to actually deprive the man of the benefits which the Select Committee desires him to obtain."

#### *Tuberculosis Committee's Report.*

Sir MONTAGUE BARLOW (chairman of the Select Committee on Pensions and deputy chairman of the Committee on Tuberculosis), alluding to the report of the latter committee, which the Government are still considering, said that, roughly speaking, the Committee found that there were some 30,000 or 40,000 tuberculous discharged soldiers. The first point the Committee desired to make was that the tuberculous soldier was only one part of the general problem of tuberculosis throughout the country. In the early stages, at any rate, the tuberculous soldier must fit into the ordinary machinery of tuberculous treatment throughout the country. In the next place, the Committee had found that the accommodation with regard to sanatoriums and hospitals was unsatisfactory and insufficient. The requirement of additional sanatoriums had got to be dealt with as it was very urgent.

Captain LOSEBY said the Select Committee had made definite recommendations in regard to the constitution of the medical boards and the constitution of the appeal board. He urged the Minister to throw these recommendations overboard. He could find a simpler method of putting up medical boards which would enable him to give the right of appeal to which every man who had been tried for his life had a right. Perhaps he would consider the proposition that a medical board might be equally competent as now if there was only one medical man upon it and two laymen. He would thus get over his difficulty of medical personnel.

Mr. LEONARD LYLE said many of the medical boards looked upon their job in the same way as a big insurance company doctor looked at his job. The point of view of the insurance doctor was to see how little he could give the men. It was his job to try to make a total disablement into a two-thirds disablement, and a two-thirds disablement into a half disablement. Medical men were just as humane as anyone else, but they had got it into their heads that if there was a doubt the benefit of the doubt must not go to the man, but to the other side. New ideas should be put into the heads of these medical boards. Some of the questions were inquisitorial to say the least. Men had been asked by a medical board what wages they had been earning.

Sir L. WORTHINGTON-EVANS: The honourable Member knows that that question has been withdrawn. The men were always told that they need not answer it unless they liked, but now no one has any right to ask the question.

Mr. LYLE said he was glad to hear it, and it would do good that such a statement had been made. Sometimes doctors did ask this question, although they were not entitled to do so.

Dr. MURRAY: Were they not originally ordered to ask the question?

Mr. LYLE said if it was not to be asked any more he was pleased to hear it.

Dr. MURRAY said that one of the most cruel duties that could be placed on medical boards was that they should be asked to say whether a certain disease was caused by, or had been aggravated by, service in the war. It was not a question that should be put to a medical board. He quite admitted that the doctors might be wrong, and in such a case the benefit should be given to the man. The position at present was illogical and unscientific, and might without difficulty be accounted an injustice. Medical reports were certainly not perfect, but it must be remembered after all that it was a new work to medical men. The doctors on these boards did not act on their own unaided intelligence, but got their orders from above.

The vote was agreed to. —

## HOUSE OF COMMONS.

WEDNESDAY JULY 30TH.

### *Medical Treatment for Officers from India.*

Colonel YATE asked the Secretary for India whether, considering the importance of the generous arrangement made by him for the treatment of civil and military officers from India suffering from tropical diseases at the hospital of the London School of Tropical Medicine, he would take steps to have his recent announcement on the subject published in India for the information of all concerned.—Mr. MONTAGU replied: Yes, sir.

### *The Use of Opium, Morphine, and Cocaine.*

Sir JAMES AGG-GARDNER asked the Home Secretary whether Regulations 40 and 40B under the Defence of the Realm Act, restricting the use of opium, morphine, and cocaine, would cease to be operative before the projected pharmacy legislation to give effect to the provisions of the International Opium Convention, 1912, had been enacted.—Mr. SHORTT replied: I hope Parliament will agree to keeping Regulation 40B in force long enough to allow legislation to be passed to give effect to the International Convention.

### *War Gratutities for Naval Nurses.*

Major Sir BERTRAM FALLE asked the Secretary to the Admiralty if he would state if any increase of pay, gratuity, or war gratuity had been, or was to be, given to the naval nursing sisters for their work.—Dr. MACNAMARA replied: I presume that my honourable and gallant friend's question refers to nursing sisters and reserve nursing sisters of Queen Alexandra's Royal Naval Nursing Service, and not to V.A.D. nursing members or British Red Cross Association nurses employed in naval hospitals. The rates of pay of reserve nursing sisters were revised in September, 1918. The rates of pay for nursing sisters (active service) is at present under consideration. We are at present in correspondence with the War Office on this point, and that department hopes to be able to give its observations shortly. No war bonus is payable to nurses, as they are in receipt of free victualling and the larger part of their uniform is provided at public expense. It has been decided to extend the War Office scheme of war gratuities for nurses to the naval nursing staff, and it is hoped to publish full details in the press at an early date.

THURSDAY, JULY 31ST.

### *Royal Army Medical Corps Appointments.*

Mr. LEONARD LYLE asked the Secretary for War if he would say on whose recommendation senior appointments were made in the Royal Army Medical Corps, and whether an advisory committee was appointed for this purpose.—Captain GUEST (Joint Patronage Secretary to the Treasury) replied: The promotion of officers to the senior ranks of the Army Medical Service is made by the Army Council on the recommendation of a Selection Board composed of Major-Generals of the Army Medical Service.

MONDAY, AUGUST 4TH.

### *Royal Army Medical Corps in Egypt.*

Viscount WOLMER asked the Secretary for War if he would say how many units of the Royal Army Medical Corps were being retained in Egypt; and whether it was proposed to send any of these home at an early date.—Mr. CHURCHILL replied: There are 51 units of the Royal Army Medical Corps in Egypt, including field ambulances, hospitals, sanitary sections, depôts, &c. As these units become surplus to requirements they are disbanded in Egypt, and the personnel, if available for demobilisation, is sent to this country for dispersal. Those who are not eligible for demobilisation are utilised for reinforcements.

### *Ex-Service Men and Tuberculosis.*

Lieutenant-Colonel RAW asked the Minister of Health whether he had considered the Report of the Special Committee on Tuberculous ex-Service Men, and when it would be made public, as the matter was one of great urgency.—Mr. PARKER replied: My right honourable friend has only

received the Report of the Committee within the last few days. He will consider it at once and discuss the matter with the Minister of Pensions, who, jointly with himself, appointed the Committee.

TUESDAY, AUGUST 5TH.

### *Treatment of Uncertifiable Mental Cases.*

Colonel WEDGWOOD asked the Minister of Health if he would state what steps he was taking with a view to providing in all areas convalescent homes for the benefit of early uncertifiable mental cases, so as to prevent their growing worse and becoming certifiable and a burden on the State; and, in order that such homes should not be regarded as half-way houses to asylums, would he ensure that intending patients should enter voluntarily and without compulsion in the same way as they would enter a hospital, and that the homes so provided should have no connexion with lunacy administration.—Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: The proposal in the first part of the question, with which I am in full sympathy, would require legislation for it to be effectively carried out. This matter, together with the important points referred to in the rest of the question, with which I am also in sympathy, are having very careful consideration between my right honourable friend the Minister of Health and my right honourable friend the Home Secretary, and it is hoped that suitable legislation for the purpose in view may shortly be introduced.

### *State Medical Service.*

Mr. LEONARD LYLE asked the Minister of Health whether any representations had been made to him with regard to the establishment of a State Medical Service; and whether, in that case, he would indicate their nature and state whether the Ministry had considered them, and with what result.—Major ASTOR: Several different proposals have reached my right honourable friend from time to time as to new schemes for public medical services. I am sending the honourable Member a copy of the reply which my right honourable friend gave on May 28th to a question on this subject from the honourable and gallant Member for Leeds, from which he will see that the development of local medical services of various kinds is certainly contemplated by the Ministry of Health; but the opinions of the consultative councils will be sought before any substantial steps on these lines will be decided upon.

### *Cholera Outbreak in India.*

Viscount WOLMER asked the Secretary for India whether he was aware that there had recently been a serious outbreak of cholera among the troops of the 6th Indian Brigade at Ali Masjid on the North-West Frontier, and that in the brigade about 400 cases and over 100 deaths had occurred; that the medical personnel attached to the brigade was not up to the establishment strength and was quite inadequate to deal with the outbreak; that there was a breakdown in the medical arrangements; that insufficient anti-cholera vaccine was available; and that the supply of saline tablets was inadequate; and whether he would cause an inquiry to be made into the matter.—Mr. MONTAGU: An outbreak of cholera in the Khyber Pass has been reported, but the number of cases in the 6th Indian Brigade was not stated. As regards the remainder of the noble Lord's question I have telegraphed for information.

### *Health of the Troops in India.*

Replying to Colonel YATE, Mr. MONTAGU stated that he had received a telegraphic report from India to the effect that orders had been issued to all generals in command that medical officers were to ask for whatever they deemed necessary for the comfort of the sick and wounded in their charge and that their demands were to be met at once. Additional hospitals for 4000 British and 8000 Indian troops had been established in specially fitted barracks in proximity to the frontier, and electric lighting and fans where none already existed were being supplied to the former. Convalescent depôts for officers and soldiers had in addition been formed, mainly in the Murree Hills. Special arrangements had been made for the supply of fresh milk to the sick in the hospital, and cows for this purpose had been placed so far as the front as Dakka, Bannu, and Tank. Scale of equipment of Indian general hospitals had been reviewed and arrangements for providing additional equipment were in progress.

NECESSITOUS LADIES' HOLIDAY FUND.—The war has reduced the income of many superannuated governesses, hospital nurses, literary ladies, companions, painters, musicians, actresses, and, indeed, all those disqualified from engaging in other lucrative work. A letter signed by the treasurer, Miss Constance Beerbohm, appeals for support in order to make a holiday possible for ladies unable to earn in the summer months. For those to whom a holiday is out of the question relief is supplied in the form of food, medicine, and clothing. The address of the treasurer is 48, Upper Berkeley-street, London, W. 1.

## Medical News.

**MEDICAL INSTRUMENTS FOR SERBIA: AN APPEAL.**—The urgent need for every description of instrument and hospital equipment prompts this appeal to the medical profession. The Hon. Mrs. Haverfield is returning immediately to Serbia to dispense the Fund for Disabled Serbian Soldiers, and will be deeply grateful to any medical men who will send to her at 9, Ennismore Gardens, S.W., any material of the indicated description.

**ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.**—At a meeting of the Council of the Royal College of Surgeons on July 24th and of the Comitia of the Royal College of Physicians on July 31st Diplomas of M.R.C.S. and L.R.C.P. were respectively conferred upon 78 candidates (including 13 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the necessary by-laws. The following are the names and medical schools of the successful candidates:—

William Stirk Adams and Robert Geoffrey Addenbrooke, Birmingham Univ.; Reginald John Allison, Manchester Univ.; James Collingwood Andrews, Cambridge Univ. and London Hosp.; Maurice Aronson, London; George Arthur Emmanuel Barnes, University College Hosp.; Cecil Bluet, L.M.S.S.A., Sydney Univ. and London Hosp.; Thomas George Doughty Bonar, Guy's; Hilda Crichton Bowser, B.Sc. Lond., and Sarah Aileen Florence Boyd-Mackay, Royal Free; William Edelstein Braceley, L.R.C.P. & S. B'n., Birmingham Univ.; Gerald Arthur Augustine Bradnack, Guy's; Ella Marianne Britten, St. George's; Anna Bridget Broman, Royal Free and St. Mary's; Harold Mallows Brown, Guy's; Nai Cheua and Benjamin Young Harper Christmas, Middlesex; Simeon Moses Cohen and Percival Charles Collins, St. Bart's; Alfred Innes Cox, L.D.S. Eng., Middlesex; Ursula Beatrice Cox, Royal Free and St. Mary's; Egbert Aubrey Lennox Crichton, King's College Hosp.; Ignatius Joseph Cruchley, London; Herbert Ernest Cumming, M.D., C.M., McGill Univ.; George Lambert Cutts, L.D.S. Eng., Guy's; Jenner Conway Davies, Cambridge Univ. and St. Bart's; Henry Dryer, Edinburgh Univ.; Clement Dunscombe, Cambridge Univ. and St. Bart's; Tyrrell George Evans, St. Bart's; Thomas Fernandez, Cambridge Univ. and Guy's Hosp.; Kathleen Field, St. Mary's; Frederic Lionel Fonseca, Ceylon Medical College and St. Mary's; Herman Meyer Gerson and Frederick John Good, London; Harold Hyman Goodman, Leeds Univ.; Dorothy Margaret Greig, Royal Free and St. Mary's; Oscar St-nley Hillman, Middlesex; Aga Mohamed Kazim, Madras and University College Hosp.; Herbert Wilfred Kerfoot, M.D., C.M., McGill, McGill Univ.; Vasant Ramji Khano'kar, B.Sc. Lond., University College Hosp.; Hyman Jacob Levy, St. Bart's; David Livingston, Durham Univ.; Eric Shaw Longton, Liverpool Univ.; Aziz Abd El Sayed Mansour, Charing Cross; Maurice Marcus, London; Alfred Marsh, Liverpool Univ.; Alfred Yaphet Massouda, Guy's; Kathleen Harding Matthews, St. Mary's; Charles Moffatt, Guy's; Vasant Ganesh Mohile, M.B., B.S. Bombay, Bombay Univ.; Frewen Moor, Cambridge Univ. and St. Thomas's; Farid Moros, St. Mary's; John Edward Blackburn Morton, Oxford Univ. and King's College Hosp.; Vernon Arthur Newton, Birmingham Univ.; John Gough Nolan, Manchester Univ.; Arthur Gordon Ord, Guy's; Edwina Ronald Ormerod, Manchester Univ.; Arthur Arnold Osman, Guy's; Sigrid Letitia Sharpe Pearson, Royal Free; Geraint Arthur Penant, Cardiff and Bristol Univ.; George Stuart Bain Philip, Charing Cross; Thomas Henry Algernon Pinning, Bristol Univ.; Hugh Reid, Liverpool Univ.; Benn Roland Reynolds, Bristol Univ. and St. Bart's; Charles Herbert St. John, Guy's; Olive Ballance Sharp, Royal Free and St. Mary's; George John Sophianopoulos, St. Bart's; Frederic Gordon Spear, Cambridge Univ. and St. Thomas's; Mary Sylvia Stocks, Royal Free and St. Mary's; James Grant Sra lau, M.B. Tr., Toronto Univ.; Sonia Strachun, St. Mary's; Stanley Roy Tattersall, St. Thomas's; Beriah Melbourne Gwynne Thomas, Cardiff and St. Bart's; Desmond Villiers Townshend, Birmingham Univ.; Alfred Basil Keith Watkins, London; Frederic Francis Wheeler, St. Mary's; Ang. s Hedley Whyte, Durham Univ.; and Gladys Mary Thurlow Williams, Birmingham Univ.

Diplomas in Public Health were also conferred upon the following 12 candidates (including one woman), viz.:—

L. D. Bailey, L.R.C.P., M.R.C.S., St. George's; M. Barker, L.R.C.P., M.R.C.S., King's College; C. D. Day, L.M.S.S.A. Lond., Cambridge Univ. and St. Bart's; H. Falk, L.R.C.P., M.R.C.S., M.B., B.C. Cantab., Cambridge Univ. and St. Thomas's; W. H. Grace, M.B., B.S. Lond., M.R.C.P., M.R.C.S., Guy's; M. J. Holmes, M.B., B.S. Melb., Melbourne Univ. and University College; T. Legge, L.R.O.P., M.R.C.S., University College; R. D. Passey, M.B., B.S. Lond., Guy's; Eva Louise Cairns Roberts, M.B., Ch.B. Manch., Manchester Univ. and King's College; W. L. Webb, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Guy's; H. E. Whittingham, M.B., Ch.B. Glasg., Glasgow Univ. and University College; and J. P. Williams, L.R.C.P., M.R.C.S., St. Mary's and King's College.

**THE ROYAL SOCIETY OF MEDICINE: A WAR SECTION.**—The proposed new section for dealing with all questions affecting medicine and surgery in the Navy, the Army, and the Air Force, has been established under the name of "War Section." The officers and council elected are as follows:—

*President.*—Surg. Rear-Admiral Sir Robert Hill, K.C.M.G., J.B., C.V.O., R.N.  
*Vice-Presidents.*—Navy: Surg.-Capt. P. W. Bassett-Smith, C.B., C.M.G., R.N. Army: Major-General S. Guise Moore, C.B.,

C.M.G., A.M.S. Air: Brig.-General Fell, C.M.G., R.A.F. India: Sir Havelock Charles, G.C.V.O. Naval and Military Auxiliary Services: Col. William Pasteur, C.B., C.M.G.  
*Honorary Secretaries.*—Navy: Surg. Lieut.-Cmdr. H. B. Hill, R.N. Army: Col. Oliver Robinson, C.M.G., A.M.S. Air: Lieut.-Col. J. McIntyre, M.C., R.A.F.  
*Representative on Editorial Committee.*—Col. S. L. Cummins, C.M.G., A.M.S.

*Representative on Library Committee.*—Surg.-Capt. P. W. Bassett-Smith, C.B., C.M.G., R.N.

*Other Members of Council.*—Navy: Surg.-Cmdr. R. Bankart, C.V.O., R.N.; Surg.-Cmdr. R. A. Ross, R.N. Army (Regular): Col. E. M. Pilcher, C.B., C.M.G., A.M.S.; Col. Sir Edward Worthington, K.C.V.O., C.B., C.M.G., R.A.M.C. (Special Reserve): Capt. C. Max Page, D.S.O., R.A.M.C. (S.R.). Air Force: Lieut.-Col. Henry Cooper, D.S.O.; Major A. P. Bowdler, Naval and Military Auxiliary Services; Major E. B. Waggett, D.S.O., R.A.M.C. (C.F.). India: Lieut.-Col. C. Tilson Hudson, C.M.G., I.M.S. (ret.); Col. G. Irvine, C.B., I.M.S. (ret.). Canada: Col. H. A. Chisholm, C.A.M.C. Australia: Lieut.-Col. J. H. Anderson, A.I.F. New Zealand: Lieut.-Col. Bernard Myers, C.M.G., N.Z.E.F. South Africa: Col. P. G. Stock, S.A.M.C. Colonial Office: Dr. A. E. Horn.

These will serve until Sept. 30th, 1920. The first meeting of the section will be held on Monday, Nov. 10th, at 5.30, when a paper will be read by the President of the Section, and it is hoped that the opening meeting will be well attended. Members, of course, are at liberty to introduce friends.

## Medical Diary for the ensuing Week.

**LECTURES, ADDRESSES, DEMONSTRATIONS, &c**  
**LONDON HOSPITAL MEDICAL COLLEGE,** in the Clinical Theatre of the Hospital.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton:—

MONDAY, August 11th.—1 P.M., Lecture III.—Dr. G. Scott: Radiological Examination of Upper Abdominal Lesions. Value of Opaque Meals.

FRIDAY.—4.30 P.M., Lecture IV.—Dr. Pantou: Test Meals. Technique for Acidity. Value of Results. Technique for Motor Power. Examination of Faeces.

A Course of Clinical Lectures for Advanced Students on Intermittent Blood Infections and their Relation to Certain Common Diseases of the Kidney, Prostate, Testicle, and other Organs will be delivered by Mr. F. Kidd:—

WEDNESDAY.—4.15 P.M., Lecture II.—Haematogenous Infections of the Prostate. Clinical Course; Diagnosis; Treatment.

## Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

COOMBS, H. M. McC., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Bedford District of the county of Bedford.

LIGHTBODY, J. H., M.D. Vict., Permanent School Medical Inspector for the Honiton District under the Devon County Council.

RAEBURN, J. A., M.D., Ch.B. Edin., D.P.H., to take charge of the Whole System of Anti-tubercular Institutions Organised for the City of Hull.

ROY, D. W., M.B., B.C. Cantab., Assistant Obstetric Physician to St. George's Hospital.

SIMMONS, A. G., M.B. Lond., L.R.C.P., Medical Registrar to Westminster Hospital.

WOODMAN, M., M.S. Lond., F.R.C.S. Eng., Honorary Aural Surgeon and Laryngologist, General Hospital, Birmingham.

Royal Free Hospital: BLAKE, Miss ALDRICH, M.S. Lond., Consulting Surgeon, with Care of Patients; DAVIS, H., M.B. Oxon., F.R.C.S., Dermatologist.

Salford Royal Hospital: JEFFERSON, G., M.S., M.B. Lond., Honorary Assistant Surgeon; WHITE, H. V., M.D., Ch.B. Manch., Honorary Ophthalmic Surgeon; SMALLEY, A. A., M.B., Ch.B. Vict., Honorary Surgeon for Diseases of the Ear, Nose, and Throat.

## Vacancies.

For further information refer to the advertisement columns.

Adelaide University.—Prof. of Path. and Bact. £900.  
Antrim County Council.—Chief Tuberc. M.O. £500.

Bath City Council.—M.O.H. and Sch. M.O. £700.  
Benenden, Kent, National Sanatorium.—Asst. Med. Supt. £175.

Birkenhead County Borough.—Asst. M.O.H. and Clin. Tuberc. O. £500.  
Birmingham City.—Municipal Bacteriologist. £700.

Birmingham General Hospital.—Two Assist. S's. £50.  
Birmingham Municipal Anti-tuberculosis Centre.—Sen. Asst. Tuberc. O. £600.

Birmingham, Rubery Hill Asylum and Annex at Hollymoor.—Med. Supt. £1250.

Bradford Royal Infirmary.—Res. Surg. O. £250.  
Brighton Education Committee.—Sen. Sch. Doctor. £600.

Brighton, Royal Sussex County Hospital.—Sen. H.S. £140.  
Cardle, Mon., Newport Royal Infirmary.—Asst. M.O. £300.

Cairo, Egyptian Government School of Medicine.—Professors and Lecturers. £E.1000 and £E.600. Also Radiologist and Lect. in Radiology, £E.500, Anaesthetist and Lect. in Anaesthetics, £E.500, and Registrar and Tutor, £E.600.

Carmarthen Mental Hospital.—Second Asst. M.O. £250.

Chartham, near Canterbury, Kent County Asylum.—Jun. Asst. M.O. £300.

Chesterfield and North Derbyshire Royal Hospital.—Res. Surg. O. £350. Also Jun. H.S. £250.

City of London Maternity Hospital, City-road, E.C.—Surg. for Venereal Diseases. Also Physician, Child Welfare Department.

Croydon County Borough.—M.O. £400.

Derby, County Borough Education Committee.—Asst. Sch. M.O. £500.

Derbyshire Royal Infirmary.—Oph. H.S. £200.

Devonport, Royal Albert Hospital.—Res. H.S. £200.

Durham County Council, Asst. Welfare M.O. £500. Also District Tuberc. M.O.'s. £600.

East Ham County Borough Education Committee.—School Dentist, £400.

East London Hospital for Children, Shadwell, E.—Cas. O. £120.

Eccles and Patricroft Hospital.—Res. H.S. £200.

Exeter City.—Asst. M.O.H. and Asst. Sch. M.O. £400.

George Town Municipality, Penang, Straits Settlements.—Asst. M.O.H. £4200.

Glamorgan County Asylum, Bridgend.—Fourth Asst. M.O. £400.

Greenwich Union Infirmary, East Greenwich, S.E.—Dep. Med. Supt. £400.

Hong Kong Government.—Bact. and Path. £600.

Huddersfield, Bradley Wood Sanatorium for Pulmonary and Surgical Tuberculosis.—Res. M.O. £500.

Khartoum, Wellcome Tropical Research Laboratories.—Asst. Bacteriologist. £E.600.

Leeds Public Dispensary, North-street.—Res. M.O. £200.

Liverpool, David Lewis Northern Hospital.—Three S.'s and Two P.'s. £150.

Liverpool Hospital for Consumption, &c.—Hon. M.O.'s.

Liverpool School of Tropical Medicine.—Tropical Research, Brazil. £300.

Liverpool, West Derby Union.—Asst. Res. M.O. £393.

London University.—William Julius Mickle Fellowship. £200.

Maldstone, West Kent General Hospital.—Jun. H.S. £125.

Manchester Royal Infirmary.—H.S.'s. £25 for first six months, £50 for second six months.

Manchester, St. Mary's Hospitals for Women and Children.—Res. Obst. S. Also Res. Surg. O. £250.

Newark Hospital and Dispensary.—Res. H.S.

Newcastle upon-Tyne, Hospital for Sick Children.—Sen. Res. M.O. £200.

Newcastle upon-Tyne, University of Durham College of Medicine.—Demonstrators of Anatomy and Physiology. £350 to £500 and £300.

Norfolk Education Committee.—Sen. Asst. Sch. M.O. £500.

Northampton County Borough Education Committee.—Female Asst. School M.O. £350.

Nottingham, Notts Education Committee.—Asst. School M.O. £425.

Peckham House, 113, Peckham-road, S.E.—Sen. Asst. M.O. £400.

Pulney Hospital, S.W.—Res. M.O. £50.

Queen Mary's Hospital for the East End, Stratford, E.—H.S.

Rochdale Infirmary and Dispensary.—Sen. H.S. £200.

Royal Chest Hospital, City-road, E.C.—Res. M.O. £200.

Royal College of Surgeons in Ireland.—Sen. Asst. (Anatomy).

St. Bartholomew's Hospital.—Phy., Surg., Asst. Surg., and Asst. Phy.-Accoucheur.

St. George's Hospital, S.W.—Two Cas. Officers. £100.

St. Mary's Hospital for Women and Children, Plaistow, E.—Dent. S. £50.

Salford Royal Hospital.—Hon. P. and Hon. Asst. P.

Sheffield Royal Infirmary.—H.S. £150.

Swansea General and Eye Hospital.—Res. M.O. £200.

Taunton and Somerset Hospital.—Res. Asst. H.S. £80.

Torquay Education Authority.—Asst. Sch. M.O. and Dept. M.O.H. £350.

University College Hospital, Gower-street, W.C.—Asst. S.

West African Medical Staff.—Number of appointments. £400.

Willesden Urban District Council.—Asst. M.O.'s. £550 to £650.

Wolverhampton and Staffordshire General Hospital.—M.O. for Venereal Clinic. £800.

Yorks, West Riding County Council.—District Tuberc. O.'s. £560.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for Certifying Surgeons under the Factory and Workshop Acts at Thorne.

## Births, Marriages, and Deaths.

### BIRTHS.

CARLISLE.—On August 1st, at "Ardlair," Heswall, Cheshire, the wife of Captain H. G. Carlisle, R.A.M.C., of a daughter.

MACCALLAN.—On July 30th, at Mandeville-place, W., the wife of Arthur Ferguson MacCallan, F.R.C.S., of a daughter.

### MARRIAGES.

ELLIOT-GREENE.—On July 31st, at St. Margaret's, Westminster, Lieutenant Colonel Henry Charles S. Elliot, O.B.E., C.A.M.C., to Margaret Kathleen Mary, daughter of the late Charles Temple Greene.

GREENISH-WRIGHT.—On July 29th, at All Saints Church, Warrington, Surrey, F. Harold S. Greenish, M.A., M.R.C.S., L.R.C.P., to Edith Marjorie, only daughter of Mr. and Mrs. Duncan Wright, of "Sibbury," Warrington.

### DEATHS.

BURRELL.—On July 30th, at Kew Gardens-road, Kew, Lionel Burrell, M.D., aged 80.

MATHEWS.—On August 1st, at College Court, Shrewsbury, Paul Mathews, M.D., aged 39.

WEEKES.—On July 31st, at Malvern, Francis Henry Weekes, F.R.C.S. Eng., M.D. Durh., aged 65.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### AN EMERGENCY CASES HOSPITAL IN THE MEUSE.<sup>1</sup>

By J. A. CAIRNS FORSYTH, M.Sc., M.B., F.R.C.S.,  
SURGEON TO THE FRENCH HOSPITAL.

OFFERED to, and accepted by the French Army, in December, 1914, our unit did not leave England until the following March, for the hospital was independent of any Red Cross organisation as regards funds, and it took some time before the means necessary to equip and maintain the formation for any length of time were obtained.

We went out with the intention of doing urgent surgery, but when we arrived at Bar-le-Duc, our destination, we found that for that class of work we were both unnecessary and unsuitable. We were a little disappointed at first, but we talked things over among ourselves, and decided that we could still do good work in the treatment of fractures, a department of surgery that was then making rapid progress.

#### Early Days in Bar-le-Duc.

At Bar-le-Duc we were given a wing of a caserne for our hospital, and it was easily adapted to our needs. The concrete barrack rooms made excellent wards, and I am afraid we scandalised the French by the open-air treatment that we gave our wounded.

We were fortunate in having for our surgeon-general the Médecin Inspecteur Mignon, a former director of the Val-de-Grâce. When the hospital was offered to the French Army as a whole General Mignon asked for it to be attached to his command, as he had a profound respect for English nursing. He was a man of deep human feeling, a great organiser, and, at the same time, a fine clinician. He quickly arranged that we should receive our wounded direct from the front, and advised the médecins chefs of the field hospitals to reserve the fracture cases for us. The system worked well. Whenever there was fighting in the Argonne we were informed at once, and our cars went up and brought down the wounded straight away.

We soon made friends with the staffs of the field ambulances, and they took great interest in our hospital, visiting it whenever they came to Bar-le-Duc. They were naturally rather envious of our fine equipment, for the French Medical Service is the Cinderella of all the Army Services. In order to be a successful médecin chef, you must have the gift of being able to make bricks without straw. Many of these men possessed that gift, and I have often been astounded at the ingenuity they displayed in making something out of nothing.

#### Visits to the Argonne Front.

One road along which we often travelled led us to Clermont. Clermont is built on a bluff in the Argonne, and must have been a very beautiful spot once, before it was burned out by the Germans. Its staircase street is rather quaint, winding up the side of the bluff to the church, which has been quite destroyed.

The local hospital fortunately was saved from destruction by the energies of a very brave nun, the Sister Gabrielle. She drove out the Germans when they entered the building to set it on fire, and rumour had it that she even had a few words of wisdom for the Crown Prince.

From Clermont, the Paris-Metz road ran west to east, and along this road were the towns and villages of Dombsale, Les Islettes, Ste. Menehould, and Braux Ste. Cohiere. In each of these were field hospitals, and at Braux there was one of the first motor hospitals, or "auto-chirs," as they were called, costly formations, but very mobile. Beyond this line were the smaller advanced hospitals, scattered throughout the Argonne, for at this time the French were doing a deal of urgent surgery close to the lines, as the Argonne roads were very bad. In one village, which was only 800 yards from the lines, they had an advanced operating centre installed in two houses. Here I saw head cases, chest cases, and abdominal cases that had been operated on, lying on the straw and doing well.

The great majority of the wounds from the Argonne were produced by bombs. It was the era of the jam-tin bomb, the "tourterelle," the "crapouillot," the "minenwerfer," and such barbarous engines of trench warfare. Gas gangrene, on the whole, was not common, but we saw enough of it to be always on guard.

<sup>1</sup> An address given at the last Social Evening of the Royal Society of Medicine and here published in an abridged form.

*The Real Frenchman.*

By this time we had got to know our soldier patients very well, and had acquired the greatest respect for them. Most of us had gone to France with only the conception of French character such as one sees on the stage, and we were agreeably surprised to find that the French soldier was a totally different being, a really very great man. At heart a child, he resembled a child in that he could find his own amusement and required no entertaining. The poilus were very skilled in handicrafts, and excelled in metal work and woodwork, and as soon as they were strong enough and able to use their hands they took to fashioning things out of bits of aluminium and shell cases. With a few simple tools they turned out beautiful rings and automatic lighters. Later on, when we moved to Faux Miroir, they specialised in the making of walking-sticks.

At Colonel Hunter's lecture I referred to their personal cleanliness, and certainly it was remarkable how they managed to keep their bodies free from lice. My own opinion, if I may give it again, is that it was largely due to the fact that the French soldier is provided with a uniform that will wash and which he is made to wash, and, in addition, he wears cotton shirts and underclothing instead of woollen. He washes his body daily—there is no false modesty among the French soldiers on that point—and he does not require a bath for his ablutions. Whatever the reasons were, we found that parasitic diseases were conspicuous by their absence, and trench fever was unknown.

*The Hospital at Faux Miroir.*

In August, 1915, we were asked to move to Faux Miroir, a château near Revigny, nine miles to the west of Bar-le-Duc. Now this château of Faux Miroir, which, by the way, was more like a Swiss hotel than a château, proved to be an interesting place, for it had been a German ambulance for two days during the battle of the Marne. The verandah had served as the operating theatre, and limbs, as they were amputated, were simply thrown over the parapet into the little plantation adjoining. The château was frequently visited by the Crown Prince during the battle, as there was a staff headquarters in the laundry. In a flower bed in front of the verandah was the grave of Hauptmann von G—, one of the Crown Prince's intimate friends, who was mortally wounded at the gate of the château and died in the salon.

All round Faux Miroir were signs of the fighting at the Marne. Three parallel rows of trenches crossed the park immediately in front of the château. In the fields, woods, and by the roadsides were many graves. Revigny itself, 3 kilometres away, on the railway from Paris to Nancy, had been much destroyed, partly by shells, partly by paraffin, for the Germans, before they retreated, set the town on fire. The Crown Prince is said to have viewed the bombardment and burning of Revigny from a dug-out at Villers-aux-Vents. It was a very palatial dug-out, for it was lined with fine old oak doors taken from the neighbouring cottages.

Close to the château, in the lee of a small wood, we built our hospital. It was hard work, as we were on 60 feet of clay, but by putting down over 200 tons of stones, slag, and gravel we made the surface sufficiently porous and dry to withstand the damp of the Meuse winters. The wards were the usual Bessanot huts, double walled, with swinging side partitions that opened outwards, so that there was abundance of air in warm weather. Each of the six wards accommodated 20 patients. The private chapel made an excellent operating theatre, as it was well lit and easily cleaned. The sacristy adjoining was converted into a preparation and sterilising room. We soon got the local ironmonger quite enthusiastic in the making of Blake splints, and we were able to employ them during that autumn and winter and find out their many advantages.

Life at Faux Miroir was much more pleasant than at Bar-le-Duc, and the change from town to country was greatly appreciated by both patients and staff. We had 600 acres of wood and park where the convalescents could roam about, and we gave them plenty of liberty, which I am proud to say they never abused. The winters were very severe, and for weeks the whole country lay deep in snow. Transport of the wounded to and from the station was then very difficult, as a high and steep hill lay between us and Revigny. In our off times during the winter we hunted the mighty hoar that came down in bands from the Argonne. The larger ones we shot and ate with great relish, the little ones we tried to catch alive with the dogs, as they made most lovable pets.

(To be concluded.)

## THE PNEUMAMETER.

DESCRIBED as a new portable spirometer, this apparatus is simple enough in detail, and after a little practice the results obtained appear concordant and relatively instructive. The principle is that of the diving bell with a small escape at the top, the bell being kept poised by the expired air of the operator, and releasing a scale which descends

uniformly by its own weight and registers the duration of expiration and therewith its actual volume on an empirical scale. To use the apparatus water is placed in the outer cylinder, the inner cylinder being removed for that purpose. The inner cylinder is then replaced, the scale which passes through an aperture at the top being brought upwards to the zero mark. A pair of levers each side of the scale keeps it in position and these are released as soon as the pressure of expired air raises the cylinder. When the operator can no longer maintain the expiratory pressure the inner cylinder falls and the descending scale is caught by the pointers or levers and held there when the reading can be taken. The breath enters by a pipe in the outer cylinder bent upwards and projecting into the inner cylinder. A rubber tube is attached with a glass mouth-piece, so designed as to prevent condensed water from the expired air reaching the mouth again. The glass mouth-piece, of course, can be sterilised.

The instrument was submitted to us by the Oliver-Pell Electric and Manufacturing Co., Ltd., of Granville House, Arundel-street, London, W.C.2.

## SMALL HOLDINGS AND THE RETURNED SOLDIER.

A NEW addition to the excellent series of guide books for ex-Service men and others, some of which we noticed in THE LANCET of May 24th, p. 922, has just been made by the Board of Agriculture and Fisheries—namely, "Dairy Farming Under Small Holding Conditions." In it the choice and management of a holding, the relative advantages of milk-selling, cheese-making, and butter-making are discussed, together with methods of production. The pamphlet can be obtained for 2d., post free, by the general public, and by ex-Service men free of charge and post free, from 3, St. James's-square, S.W.1. The Board of Agriculture and Fisheries have also issued a pamphlet, which can be obtained post free from the same address, on "Apple Aphides." This is an abridgment of an article which recently appeared in the *Journal of the Board of Agriculture* from the pen of Mr. F. V. Theobald and deals with the life histories and the methods of destruction of some of the aphides which infest apple trees.

## AN IMPROVEMENT IN THE GALVANOSSET APPARATUS.

AN improvement of some importance in the rheostat, known as the Galvanoset, is announced by the Medical Supply Association of 167-185, Gray's Inn-road, London, W.C.1. The four conducting elements were formerly made of carbon, but the positive element of this material tended to crumble and discolour the water, which necessitated frequent changing of the water and replacing the carbon. This disadvantage is entirely removed by adopting a positive element of platinum. The improvement is an obvious one, and those who have been using the Galvanoset apparatus may be glad to know that this change can readily be made, and what was a source of inconvenience can be avoided by this simple adjustment.

## Clinical Observations

IN

## INDIA DURING THE WAR.

By A. W. SHEEN, C.B.E., M.S., M.D., F.R.C.S.,

COLONEL, A.M.S. (T.F.); FORMERLY O.C. No. 34 (WELSH) GENERAL HOSPITAL, INDIA, AND CONSULTING SURGEON, WAR HOSPITALS, INDIA; CONSULTING SURGEON, KING EDWARD VII. HOSPITAL, CARDIFF.

THE following are brief observations which seem of interest, made during nearly three years in India. They are not meant to be exhaustive and I have confined myself to conditions peculiar to the tropics and mainly to India.

**War wounds.**—The gunshot wounds coming back from Mesopotamia did not suppurate either so often or so freely as those sustained in France. Many presented the clean "in and out" character of the South African war wounds. This is probably because the soil of Mesopotamia is not so infective as the highly manured soil of densely populated and elaborately cultivated countries like Belgium and Northern France. Tetanus and gas gangrene were infrequent, almost the only cases that I saw in India being in wounded Turkish prisoners, who had, before coming into British hands, been—perhaps unavoidably—inadequately treated.

**Anæsthetics.**—I am convinced that ether can be given in India. In 1916, on arrival, I was fortunate in having under me officers who could give "open ether," and it became the routine anæsthetic. Later the details of an "open ether" series of cases were carefully recorded at one of the Bombay war hospitals. The operations were in May and June, the hottest time of the year, with the temperature between 90° and 100° F. Scopolomorphine sometimes, but not always, preceded. The majority of the operations were abdominal. No difficulties were experienced in any case; the amount of ether given was not excessive. In India with ordinary precautions there is no difficulty in keeping ether. It could be manufactured there with a little enterprise.

**Operating and operation theatres in hot climates.**—To prevent sweat dropping on to the wound area special assistants dab the faces of those concerned in the operation with the ends of rolled towels or with mops on handles. A small mouth mask should be worn. Through a large-type face mask one perspires and cannot be mopped. Bacteriological investigation of the sweat on several occasions universally gave a pure culture of *Staphylococcus albus*. The following is probably a case of sweat wound infection.

On a hot day the femur was plated with two heavy plates in a simple fracture; skin was carefully excluded. There was a slight evening rise of temperature, usually 99.2°. Except for this all went apparently well until between five to six weeks after the operation, when a point of sero-purulent oozing appeared in the wound line; this gave a pure cultivation of *Staphylococcus albus*. Later, after bone union, the plates were removed and every one of the screw-holes tested gave a similar cultivation. Cases such as bone-plating should be removed to a cool place for operation.

A fan in the theatre is unobjectionable; the air near it showed no more organisms than in other parts of the theatre. A case of neck suppuration led me to advise that the long-haired, full-bearded Sikhs should wear sterile linen fitted covers for head and beard during operations on them. A roof light is not usually found in Indian theatres. Sterile tops for all concerned would be a ludicrous addition to the equipment! There is no objection, however, to a sloping north roof light of the long and narrow type continuous with a narrow north window. Too big a north window is to be avoided. I know of one "war" theatre where practically the whole north wall is glass, making it a veritable hot house. The room where the sterilisers are should not be continuous with the theatre, but cut off by an open corridor—i.e., one with a roof but no sides.

**Orthopædics.**—The principles of military orthopædics have been so often and so well enunciated that I will not give more than the briefest summary of my views. They are embodied at length in the *Indian Medical Gazette*.<sup>1</sup> The treatment of these cases should be preventive from the

beginning; it is necessary that there should be quick return from the active war areas and segregation in a few large special hospitals where all the necessary specialists and the special treatment materials are assembled. I had to combat the idea that British "orthopædics" could wait until they got to England to be treated. Many could be cured and sent back to duty. For those—a minority—who had to go home I recommended "orthopædic" equipment on the hospital ships.

The cases in Indians presented some special features. A number were largely functional, and amongst some of these patients—as those who know the country will realise—a disability is regarded as an asset. Particularly it was found that special physical drill was very valuable in curing functional deformities, and on the parade ground the motionless arms or legs would gradually be seen to move more and more in concert with the limbs of the others exercising. In this connexion it is interesting to call attention to the great use the Germans have made of this form of treatment.

**Head cases.**—A number of cases of head wounds which had gone to England and, being apparently well, had been sent back to Mesopotamia came under my notice in that, having been a very short time in Mesopotamia, they were invalided to India with headache or other symptoms. My conclusion was that head wounds should not be returned to a hot climate. I saw my colleague Major L. B. Rawling's cases of decompression for epileptiform attacks following heat-stroke, and can testify to the benefits of the operation.

**Oriental sore.**—This cutaneous or subcutaneous malady, due to the infection of the tissues with *Leishmania tropica*, is of great interest. Its names are protean: Delhi boil, Bagdad boil, Aleppo boil are some of many. The cases which I saw all came from Mesopotamia. Sand-flies have been suggested as a possible source of infection. In typical cases the diagnosis is easy—a more or less scabbed, sloughy, often circular ulcer, usually on exposed parts of the body. Diagnosis is confirmed by finding the typical parasite in scrapings or, better, by puncture of the edge. The subcutaneous form is often most puzzling. In a case shown by Lieutenant-Colonel R. Row, I.M.S., to the Bombay War Hospitals Medical Society there was a group of keloidal swellings, each about the size of an almond, over the left scapula; in a nursing sister, whom I saw with Captain H. Weir, R.A.M.C., there was a bluntly pedunculated sphere on the lower lip the size of a large marble, pale, shiny, cedematous-looking, of six months' duration. Diagnosis in these two cases would have been impossible without the aid of puncture. I saw many cases in British soldiers and several in nurses.

As with many diseases which spontaneously tend to get well, numerous forms of treatment have been credited with success. Colonel Row gave a vaccine prepared from the parasite and dressed the sores with salol in oil. I have seen good results from salvarsan and from X rays. Other measures, such as scraping, ionisation, and the application of antiseptics or caustics, sometimes apparently cure but are followed by recurrence. Intravenous injection of antimony tartrate is usually successful. A good treatment for small sores suitably situated is complete excision. Microscopical examination of the excised sore shows down-growing columns of cells with cell-nests indistinguishable from epithelioma. This has an interesting bearing on the ætiology of cancer, and it is to be remembered that the South American nasopharyngeal form of the disease is known as "Leishman cancer."

Regarding infection, Colonel Row called my attention to a flagellate found in the latex of plant juice (*Euphorbia*) which strongly resembles, morphologically and culturally, the flagellate form of the Leishman body. As the incubation period of oriental sore may be prolonged to five or six months, and as apparently healed cases may recur, the disease should be borne in mind in the home country.

**Kangri canoer.**—A visit to Srinagar in Kashmir gave me an opportunity, through the kindness of Dr. Ernest Neve, of visiting the excellent mission hospital there and learning something about this disease. The Kashmiri keep themselves warm during their very cold winters by hugging to the abdomen under the clothing a kangri, which is an earthenware receptacle about 4 inches across enclosed in basket work, this being continued into a curved-over handle. In it is kept glowing wood ash. Minor skin irritation, staining, or

<sup>1</sup> "The Principles of Military Orthopædics, with Notes on the Constitution of an Orthopædic Hospital," *Indian Medical Gazette*, vol. III., No. 9, September, 1918.

ulceration are common results and sometimes cutaneous cancer develops. I saw Dr. Neve operate on one case. The patient, a man, aged 60, had a large circular median growth below and including the umbilicus; it was removed with muscle and a portion of peritoneum. In this case the growth was recurrent, the original operation having been done six months previously. For the following facts I am indebted to Dr. Neve. The cancer occurs in skin irritated or actually burnt from kangris. As well as the abdomen, the fronts of the thighs are affected from squatting. Though this growth is below the umbilicus the glands in the axillæ must be examined, as they may be affected. It is best to remove the groin glands when operating, even if these are not obviously affected. The disease is more frequent in people who have warts or moles about them. The man whom I saw operated on had a pigmented mole on his forehead. Dr. Neve had never seen a case under 30.

*Guinea worm.*—It would puzzle anyone unacquainted with this infection to know the meaning of an earthenware receptacle of water suspended some feet above the leg of a patient, while from a small hole in its bottom water drips on to an opening in the patient's leg, from which a whitish thread protrudes. This is a method of coaxing out the worm. The worm—always a female—lies under the epidermis. It tends to emerge, and this may be hastened by injection of various antiseptics. When, as occasionally, closely coiled the worm can be excised in toto; rarely it protrudes as a loop. The native method of abstracting it is by twisting the protruding portion round a stick, giving a turn or two daily. Castellani suggests that the worm is the fiery serpent of Moses; if this is so, the badge of the R.A.M.C. shows this method of abstraction! The worm should never be pulled upon, for if it breaks in the tissues it sets up an intense gangrenous cellulitis, often fatal; I saw two cases of this kind which died. The worm is mostly uterus, and the uterine contents appear to be intensely irritating to the tissues. The method of treatment is, of course, alluded to in some text-books.

*Inguinal bubo.*—I saw quite a series of cases in which no source of infection was demonstrable, the majority being in Colaba War Hospital under the care of Captain G. W. Bury, R.A.M.C. The patients were British, the greater number being sailors. The glands enlarge and soften and excision shows broken down gland tissue and sero-purulent material. Cultivations were invariably reported sterile. The wounds often broke down aseptically and were slow in healing. I understand that cases of "Oriental bubo" are common amongst natives in the Madras district. The occurrence in sailors suggests infection through the bare feet, but no evidence was found in support of this.

*Leprosy.*—Of very great interest was a visit which I, in common with a number of other medical officers, paid to the leper asylum at Matunga, Bombay, on the kind invitation of Dr. Arthur Powell. The patients were mostly Hindoos, and the majority had lived near the sea. Dr. Powell pointed out the roughened, wrinkled, reddened skin like an orange; frequent enlargement of the nipples, constrictions round the fingers like ainhum, depressed nose bridges, hoarse voices from nodules on the laryngeal cartilages, mixed cases—i.e., both nodular and anæsthetic, the light-coloured anæsthetic areas, cases showing ulnar griffe; others, weakness of the anterior tibial muscles. "Nastin" and other remedies had been tried without success. The bacillus is not pyogenic. It can be got from the liver and spleen. The patients die of tuberculosis or other intercurrent disease.

In the visitors' book we saw the signature of Jonathan Hutchinson in 1903 and his written expression of opinion that no harm would come from selling flowers gathered by the lepers in their gardens, but that other people should not eat food prepared by lepers' hands.

*Cholera.*—Nothing struck me more about cholera than the urgency necessary for its treatment. To get cases early and to treat them early is to save their lives. The cholera outfit should be as ready and as handy as the tracheotomy box. The copious hypertonic saline intravenous infusions and the free oral administration of permanganate of potash are—as discovered and so ably advocated by Sir Leonard Rogers—truly life-saving procedures. I was glad to hear the presidential address of Sir Leonard Rogers to the Indian Science Congress at Bombay in January of this year, when he told us that his latest results showed a mortality of only 14.9 per cent.

*Plague.*—It is difficult to believe that this—perhaps the greatest scourge of India—only last invaded the country in 1896. Besides the rat, a little squirrel, known as the tree-rat, almost universal in India, can become infected. It seems to me that what is wanted in India is not so much laboratory research in plague as sending out amongst the people "missionaries" of their own race and class to teach them what to do to avoid plague and how to act if it occurs.

*Malaria.*—Of the numerous malaria patients a certain proportion came under surgical attention for this or that reason. I saw three cases of musculo-spiral paralysis following intramuscular quinine injections into the upper arm; in two of these the nerve had been freed from fibrous tissue and they were recovering. My experience is that aseptic operations do not set up an attack of malaria in patients who have parasites in their blood but no active symptoms. The patients were usually taking quinine at the times of the operations. I saw arthritis attributed to malaria.

I saw also sufferers from dysentery, scurvy, the typhoid group, influenza, and tuberculosis.

*Dysentery.*—I saw thickened transverse colon, cases of general tumidity of the abdomen, arthritis of knees and of ankles, and rectal ulcer which had been diagnosed as cancer. With regard to carriers, my colleague, Captain W. MacAdam, R.A.M.C., found proportionately more amongst the general hospital population than amongst the cases labelled dysentery.

*Scurvy.*—There were at one time many cases in Indians, and I am afraid the lime juice issued was not always a prophylactic. A series of leg sores, many apparently resulting from slight injuries, yielded readily to antiscorbutic treatment, Dakin's fluid proving the best dressing for the ulcers. The hæmatoma in the calf or elsewhere resulting from scurvy is puzzling to diagnose if one is not on the look out for the disease.

*Typhoid group.*—Amongst the complications I saw phlebitis with leg ulcer; osteitis of tibia, humerus, and metacarpals; paralysis of deltoid with pectoralis major; a case under Lieutenant-Colonel T. S. Novis, I.M.S., where the muco-pus from the gall-bladder gave a pure cultivation of paratyphoid A; another case, on which I operated, a long-standing carrier, in which the gall-bladder contents were sterile. I wish that the surgeon had been called upon to drain the gall-bladder and the bacteriologist to investigate its contents in more of these carrier cases. A curious case of bilateral swellings in the posterior knee region following typhoid showed nothing but muscle on incision. A *B. coli* infection of the urine occurred occasionally after typhoid; the patients had puffy, pasty faces. An autogenous vaccine usually, but not always, cured.

*Influenza.*—Amongst the surgical complications I noted two cases of suppurative parotitis, one bilateral. From the pus of the latter pneumococcus was obtained in pure culture.

*Tuberculosis.*—There seemed an unusual incidence of surgical tuberculosis of bones, joints, glands, and abdomen in Indians who had been in France. Special institutions are badly needed for the treatment of these cases.

*Snakes.*—Cobras and kraits were a *bête noir* in my hospital area, and one walked about at night with a lantern. The antivenine and other necessary equipment for treating snake-bite were always kept ready in the emergency receiving room. Antivenine is useless for krait-bite. It was interesting at the Bombay Bacteriological Laboratory to see the snakes handled. They bit into material stretched tightly over the top of a wineglass, the venom being milked out of their glands into the glass. Then they were fed with a milk preparation through a funnel. The Russell's viper was the fiercest of all. The man who handled the snakes was rumoured to get the munificent sum of 10-15 rupees a month!

*Ulcers.*—Bites of mosquitoes and other insects sometimes develop into ulcers which were slow in healing. At Secunderabad I saw a case of ulcer of the ankle which had given a pure cultivation of a diphtheroid bacillus, and I was told that there had been a regular epidemic of similar cases elsewhere.

*Madura foot.*—I saw one case of this in an Indian. It had started three months previously at Samara, and was attributed to the kick of a mule. There was a large puffy swelling over the inner ankle in which were several sinusses from which pus could be squeezed showing the characteristic yellow granules.

*Bilharziasis.*—This I saw successfully treated by Captain T. B. Heaton, R.A.M.C., with intravenous injections of antimony tartrate.

*Bugs.*—These are the plague of Indian barracks and most difficult to get rid of. To deprive them of their proper nutriment by emptying the barrack of its human inhabitants is not much good, as one realises by recalling Shipley's statement that a bug can live for a year without nourishment, although at the end of that time it is so thin that you can read print through it. We had most success by generating HCN and letting it into the barrack, emptied except for its furniture and bedding. The louvred roofs of the barracks are, however, difficult to seal. The HCN machines are used by railway companies in India for their carriages. The smell of prussic acid wafted over the barracks of a 3000-bedded hospital is most impressive.

For bedsteads total immersion in a special tank of boiling water is, of course, effective. This method I saw in use at Secunderabad. Wooden bedsteads and wooden mosquito poles are to be avoided; the bugs get into all the cracks. Apart from the above, painstaking cleaning of bedsteads and furniture and sterilisation of bedding and clothing are the best remedies.

#### Conclusion.

In conclusion, let me say how fresh and varied in medical experience is India to the newcomer, and I hope that these random notes will do something to convey this interest to others. I trust that the Medical Service of India, remodelled as it should be, with its manifold opportunities for interesting practice and its general attractiveness, will never cease to command the best trained members of the profession.

## MATERNAL MORTALITY IN CHILD-BED.

By SIR JOHN PHILLIPS, M.A., M.D. CANTAB., F.R.C.P.,

HONORARY PHYSICIAN TO HER MAJESTY QUEEN MARY; CONSULTING OBSTETRIC PHYSICIAN TO KING'S COLLEGE HOSPITAL; AND EMERITUS PROFESSOR OF OBSTETRICS IN KING'S COLLEGE.

CAN maternal mortality in childbirth be further reduced?

At the present time, when most medical men interested in obstetrics are studying eugenics and antenatal pathology, it behoves one to produce all possible evidence in the hope of arriving at improved results and diminished maternal mortality. I have thought it might be of interest, and possibly helpful, to give an abstract of 35 years of midwifery in private practice. No record of a large number of cases under these circumstances has recently been published, and a comparison between the results obtained in private practice and in public institutions may lead to useful conclusions. I have looked up the notes of all the cases of pregnancy and labour for which I have been personally responsible during 35 years and I find that in round numbers the total is 2100. I met, unfortunately, with seven maternal deaths, of which I give abstract notes below, taken from full records made at the time.

#### *Reduction of Septic Mortality and Morbidity in Special Hospitals.*

The great risk of labour in the "seventies," and previously, was puerperal fever. The records of special hospitals and lying-in wards at that time make dismal reading, for they speak only of repeated outbursts of what is now known as streptococcal infection and the usual heavy toll of deaths, with consequent closing down of the wards.

The introduction of antiseptics in the late "seventies" gradually changed all this, and although the first attempts at grappling with the germ were not very successful, still, by continued effort, such an improvement resulted that for some years now streptococcal infection may be said to have been practically banished from lying-in hospitals and the obstetric wards of general hospitals, although occasional outbursts are from time to time reported in outlying districts.

As an obstetric clerk I remember officiating at several labours under the carbolic spray; nothing could be more disagreeable for patient and attendant, and the absorption of the carbolic acid occasionally produced carboloria and pneumonia. Anyone interested in the subject has only to refer to the late Dr. Robert Boxall's interesting and

exhaustive paper on "Fever in Child-bed,"<sup>1</sup> read before the Obstetrical Society, in which he showed from the statistics of the General Lying-in Hospital how by gradual experiments in various antiseptics, beginning with permanganate of potash, followed by carbolic acid, and, lastly, by mercury, septic mortality and morbidity was steadily reduced.

During the last few years asepsis has somewhat replaced antiseptics; by that I mean sterilised dressings and gloves being used in place of strong antiseptic solutions. I must confess, however, that I know of nothing safer than the spirit solution of 1 in 1000 hydrarg. biniodide.

#### *Care of Mother in Pregnancy and Puerperium.*

Although streptococcal infection may be said to be a preventable accident, another formidable infection exists in *Bacterium coli*, the ravages of which are not yet fully grasped. The frequently depreciated health in pregnancy, especially among the poorer and ill-fed classes, is a fertile cause of this bacillus over-riding its natural barriers and infecting outside organs, especially the bladder, liver, and kidneys. In a recent paper I have endeavoured to show that very grave and even fatal results may occur from infection of the bile ducts by this organism.<sup>2</sup> The gonococcus, it need hardly be stated, is a formidable complication of the pregnant condition and may lead to a permanent disablement from infection of the tubes.

Pregnancy and labour are still looked upon by a large number of the laity as perfectly normal processes, but my experience, and I think that of hundreds of others, is that with our present conditions of life such is not the case.

I have always advocated the regular pelvic examination of women during the whole of pregnancy and the puerperium, in addition to a careful pathological examination of the excreta. When a patient misses a period and presumes herself pregnant a pelvic examination will reveal the possible presence of an ovarian dermoid cyst or uterine fibroid or other pathological condition which could be satisfactorily treated at the time. Examination at intervals should show a steady increase in the size of the uterus and an absence of any pathological products from the urine or faeces. Pelvic measurements are of great importance, and should there be the slightest suspicion of diminution or disproportion in any of the diameters of the pelvis the patient should be examined at fortnightly intervals, from the thirtieth week onward to term. Any deposit in the urine not clearing up by boiling should arouse a strong suspicion of bacilluria, and the practitioner should not be content with an ordinary test-tube examination.

It has also been my custom during the lying-in period to measure the level of the uterus daily for the first week, and to examine the pelvis internally at the end of a fortnight, and again at the end of three weeks, when the patient rises from her bed; subinvolution and retroversion of the uterus and unhealed lacerations are in this way detected.

#### *Abstract of Fatal Cases.*

I now append a short abstract of each of the seven fatal cases.

##### *Acute Peritonitis.*

CASE 1.—Aged 35, a 5-para, all at term. Pains began a month prematurely, vertex presentation, the labour lasted nine hours and delivery was natural and easy, a male being born alive. At the last labour, two years before, she had an acute attack of pain in the right iliac fossa, with temperature; this subsided and she remained quite well until a few days before the onset of the present labour; she then had several severe attacks of pain in the right iliac fossa, with temperature; labour came on prematurely during one of these attacks and continued after the labour. The patient died of acute peritonitis after 36 hours' illness; she was very weak and ill during the labour, with a rapid pulse and a hot, dry skin. A post-mortem was obtained, which showed general peritonitis over the lower abdomen, its focus being a gangrenous appendix lying in a cavity of putrid pus, the size of an orange.

It must be noted that this case occurred in 1883, at which period the pathology and treatment by operation of disease of the appendix was not sufficiently recognised; had I seen this case at the present time no doubt the proper course would have been to open the abdomen before labour commenced, and a satisfactory issue might have resulted.

<sup>1</sup> Obstetrical Transactions of London, 1889, xxxii., 215, 275.

<sup>2</sup> Hepatic Toxæmia, Royal Society of Medicine, Obstetrical and Gynecological Section, 1916, 115.

I have contributed a short paper on this subject entitled "Acute Peritonitis (without Discovered Cause) Complicating Pregnancy and Labour."<sup>3</sup>

In this is related the case of a woman, nearly seven months pregnant and in good health, who fell over a chair-back on her left side. Much pain and persistent vomiting followed. She was found in a very serious condition, her abdomen distended, pulse 120, temperature 103° F., and respirations 48. Though no proper pains could be distinguished, labour came on and terminated very quickly. Her condition became rapidly worse, her abdomen was opened and general peritonitis found, but no apparent cause. Free drainage was carried out, but the patient died in the course of a few hours.

Cases of a similar nature described by Simpson and Gow are too sparse in their details to draw any satisfactory conclusion from.

#### "Russian" Influenza.

I believe this to have been one of the earliest cases of what was then called "Russian" influenza. I was attacked with the same malady within 24 hours.

CASE 2.—Aged 27, seven children. When 8½ months pregnant she was seized with a sharp rigor and all the symptoms of the disease we now call epidemic influenza. Bronchial catarrh rapidly ensued, with distressing dyspnoea and blueness of the face. There was a large amount of liquor amnii present, and, as the cervix was thin and soft and admitted three fingers, in order to relieve her distress the membranes were punctured. Temporary relief to the dyspnoea was given, labour came on rapidly, and a living child was born, followed by a short amelioration of the symptoms, but the bronchial affection rapidly increased and she died in great dyspnoea within 24 hours of the labour starting.

This case fully bears out the experience of the epidemic of 1918, where advanced pregnancy complicated by this disease was in a large proportion of cases fatal in a few days from septic pneumonia, no remedy appearing to have any power to check its progress.

#### Hæmorrhage.

CASE 3.—The patient, a 2-para, whom I had attended three years before with a somewhat difficult labour, was again 38 weeks pregnant. She was then in the country, and without any warning she was seized with severe hæmorrhage. As soon as she had sufficiently recovered from this she was driven up to London, and, unfortunately, during the journey she passed over a level railway crossing at somewhat high speed. She was badly jolted, and a return of the hæmorrhage took place before reaching her journey's end. When I reached her I found her almost pulseless, with the cervix two-thirds dilated and the edge of the placenta presenting posteriorly. I therefore ruptured the membranes and proceeded to endeavour to restore her by venesection and saline injections. She did not respond very well to this treatment. In the meantime the hæmorrhage all ceased, labour pains came on, and the head descended into the pelvis. Immediately on full dilatation of the cervix I applied the forceps without an anæsthetic and lifted the child out quite easily; it was stillborn. For an hour she tended to improve under the action of the usual restoratives, but after that she rapidly sank without any further hæmorrhage.

Had I seen this case during the first hæmorrhage the obvious treatment would have been a Cæsarean section, but her condition after the second hæmorrhage was so grave that no possible attempt at operation could be made.

#### Concealed Accidental Hæmorrhage.

CASE 4.—This patient, a 2-para, was at full term and was suffering from cardiac trouble, namely, pericarditis with aortic stenosis. She remained fairly well until the day of the labour. I had previously ascertained that the presentation was a vertex and the pelvic condition normal. Her pulse, however, was small and quick, much accelerated by any exertion; there was no albumin or swelling of the feet. She was suddenly seized with abdominal pain while at lunch on the day of her labour. On seeing her about an hour afterwards I found her in a collapsed condition, the uterus being hard and tender. Labour pains were slight, but the cervix was slowly dilating. All attention was therefore directed to her general condition, oxygen was given to inhale, salines were injected with strychnine and musk subcutaneously, but none of these remedies appeared to produce any improvement in her pulse. When the os uteri was fully dilated I applied the forceps and delivered easily without an anæsthetic; the child was stillborn. Immediately on delivery two measured pints of recent blood clot escaped. She slowly sank, and died in about an hour.

This is quite a characteristic case of concealed accidental hæmorrhage. The cardiac complication was most unfortunate. I treated her on the lines generally laid down in my article on "Pregnancy and Cardiac Disease."<sup>4</sup> It is difficult to decide to what exactly to ascribe the patient's death. In two similar cases of concealed accidental hæmorrhage which I have encountered, a larger amount of blood was lost without producing more than an ordinary amount of temporary shock, and in both cases the child was alive, though in each case resuscitation was difficult. She had been warned against pregnancy by more than one authority on heart disease, so that apparently the extra strain of pregnancy and then the hæmorrhage were sufficient to produce what must be termed "shock." Quite possibly had the drug pituitrin been in existence it might have done something towards saving her life. If the cardiac condition had been more sound, I think Cæsarean section would have been indicated.

#### "Hepatic Toxæmia."

CASE 5.—This case is described under "Hepatic Toxæmia," (Case 1).<sup>5</sup> The patient was a primigravida, with well-marked pelvic contraction, for which induction of labour was carried out. For some weeks before labour sickness and prostration had been observed. Labour was quite easy and delivery natural, and there was no apparent reason for the child's stillbirth. The progress of the case immediately after labour was most unsatisfactory, the vomiting continued and shortly afterwards contained altered blood. Jaundice supervened and the patient died in 48 hours, with a temperature of 110°. A post mortem was obtained and a difference of opinion occurred as to the exact cause of death, one of the pathologists considering it a case of acute yellow atrophy of the liver, and another, hepatic toxæmia.

Assuming that this was a case of acute yellow atrophy of the liver, it is the only one of the kind that I have ever encountered. I believe that such cases are uniformly, rapidly, and progressively fatal, no remedy having, so far, been discovered.

#### Pregnancy following Abdominal Uterine Fixation.

CASE 6.—This patient, a 6-para, had not been pregnant for seven years. She had had uterine fixation for prolapsus, which had improved her health very much. I did not see her until the thirty-eighth week, when a very serious condition of things was present. The fœtus was lying transversely in the abdomen in a hi-lobed swelling, the narrow portion of which was produced by adhesions from the old operation. The head lay in one dilatation, the buttocks in another. At a consultation the question of Cæsarean section or immediate induction was discussed, and the latter decided on. The labour proceeded quite quietly until dilatation of the cervix was sufficient to bring down a leg. I carefully turned and was surprised how easily it was brought about. Labour terminated rapidly, a living child being born; the placenta was expressed in the ordinary course and the patient appeared quite well for an hour. She then became faint, and, although there was no hæmorrhage and I had explored the uterine cavity to eliminate any question of rupture of the uterus, she died in spite of all attempts to restore her.

It appeared that on two other occasions at her labours she had nearly succumbed from heart failure without any apparent reason, and it is quite probable that the stretching of the adhesions between the uterus and the abdominal wall during labour produced reflex inhibition of the cardiac apparatus. This case was an instance of the risk that attends pregnancy following an abdominal uterine fixation. In the old operation the sutures were passed through the fundus uteri, which prevented dilatation as the pregnancy advanced. In the more modern operation the sutures are passed low down, thus allowing dilatation of the fundus without producing either a miscarriage or difficulty at labour.

#### Secondary Post-partum Hæmorrhage.

CASE 7.—This patient, a primigravida, was at full term. The labour was a long and lingering one owing to slow dilatation of the cervix and an occipito-posterior presentation. The cervix was finally manually dilated, the head was rotated with the forceps, and delivery carried out. No complications followed, the placenta being easily expressed, and no hæmorrhage occurred. Forty-eight hours after labour her child had a slight convulsion, and an unwise relative walked hurriedly into the room and told her of it. I had seen both mother and child about two hours before and both were doing well. Almost immediately on receiving the news she had a violent secondary post-partum hæmorrhage and

<sup>4</sup> Practitioner, June, 1895, "The Management of the Pregnant, Parturient and Lying-in Woman Suffering from Cardiac Disease."

<sup>5</sup> Royal Society of Medicine, Obstetrical and Gynaecological Section, 1916, p. 115.

died within an hour, despite uterine plugging and the usual restoratives. I might add, however, that she was one of the most nervous and apprehensive patients I have ever attended.

#### *Statistical Data.*

The question to consider is, Can the present percentage of maternal mortality in child-bed be further reduced? This mortality may vary very much according to whether the labour takes place in a special ward, in private practice, or in outdoor maternity practice.

For instance, in 1916, in the outdoor department of the Ladies Lying-in Charity, Liverpool, 1086 cases were attended by midwives, with 2 deaths (0.18 per cent.).

At the General Lying-in Hospital in 1917, 870 cases were attended, with 5 deaths (0.5 per cent.), and in 1918, 914 cases, with 6 deaths (0.6 per cent.).

My own experience in special practice amounts to 2100 cases, with 7 deaths (0.3 per cent.). At a home for officers' wives, where labours are carried out under the best possible conditions and where all the patients are examined and reported on beforehand by myself, 240 were attended in 20 months, with 1 death (0.4 per cent.). This death occurred a few days after a normal labour owing to a severe abdominal operation for old-standing intestinal obstruction, a condition which had arisen independently of the pregnancy.

The mortality of every variety of practice thus varies from 0.18 per cent. to 0.6 per cent. These divergencies of results may be accounted for in many ways. At a lying-in hospital all the serious cases are admitted, some of them in a state of acute sepsis, others moribund from delay in delivery; and, I think, the statistics of the General Lying-in Hospital may be considered a very fair indication of the results obtained in the class of cases admitted to such an institution. There is also the element of what can be called "chance"—for instance, my first two cases occurred in a short run of 40 labours; then followed an unbroken series of 636 cases without a death.

In private practice the patients are generally well-to-do, in healthy surroundings, and under the care of the family doctor. This class should be more likely to produce a low percentage of mortality than a lying-in hospital, where the patients have often been ill-fed, have lived in filthy surroundings, and may be admitted in an already infected condition.

#### *Prospect of Reduced Mortality.*

In studying the cases of death in my practice we have to consider whether any different treatment would possibly have saved any of the seven cases. The chief advance resulting from the antiseptic system is, no doubt, the perfection of Cæsarean section. This operation is now applied with the greatest success in a much extended class of case, more especially in placenta prævia occurring in primigravida; and in selected cases in multipara; in concealed accidental hæmorrhage, and in most cases of puerperal convulsions in first labours. Thus it is quite possible that Cases 3 and 4 might have been saved by a prompt Cæsarean section. Case 1, under modern treatment, would also in all probability have been saved. Were I to meet a case similar to No. 6 again I should be inclined strongly to advise Cæsarean section in place of induction. If Case 5 was acute yellow atrophy, then it was practically hopeless from the onset of the disease, as I know of no case of recovery under those conditions. Finally, the last case, No. 7, was one of those accidents outside the control of the medical practitioner, but it serves as a warning to those who think that excitement is not harmful to the lying-in woman. Although Cæsarean section can be properly applied more extensively, I feel that the tendency is for the pendulum to swing in a somewhat extreme direction, and that in many cases of slight pelvic contraction, in which Cæsarean section is resorted to, an equally good result might be obtained by induction of labour.

From these statistics it is clear that maternal mortality in child-bed is certainly in process of being reduced, and the question now is whether we have at our disposal any means to reduce this mortality further.

Another important complication of pregnancy—namely, what is called "pregnancy kidney"—may, I trust, ultimately be treated successfully when the physiological chemist has discovered its cause. Vaccine treatment may also be expected to be much in evidence, especially against toxins and *Bacterium coli*.

With regard to the use of scopolamine morphine (twilight sleep), my own experience is that, although in some cases it acts like a charm, its results are not sufficiently reliable, and it certainly is not free from risk to both mother and child.

## THE CONDUCT OF LABOUR AND PUERPERAL SEPSIS.

By J. H. E. BROCK, M.D., B.S. LOND., D.P.H.,  
F.R.C.S. ENG.,

LATE HONORARY PHYSICIAN TO THE WESTMINSTER GENERAL DISPENSARY

FROM that large majority of general practitioners who accept midwifery as part of their usual work, the dread of puerperal sepsis is never absent. When looking back nearly 40 years one contrasts the methods of that day with the present technique the enormous improvement is borne in upon one. To gauge results by hard figures is to admit, however, the comparatively small reduction in the mortality rate from puerperal sepsis. Indeed, the returns for the last 70 years prove that, for some of the earlier years, the death-rate was almost identical with some quite recent ones. Dr. Victor Bonney,<sup>1</sup> in his admirable address on the Continued High Maternal Mortality of Childbearing, the Reason and the Remedy, deplores that, while in every other domain of surgery death from sepsis has almost been abolished, in midwifery it has hardly diminished.

Some points bearing on the question have not, in my opinion, been sufficiently brought into the light of day, or made to bear the responsibility rightly belonging to them. I believe the reason for the high death-rate from puerperal sepsis resides in these facts; and not until their proper importance in the conduct of labour is accorded to them can we hope to attain asepsis.

#### *A Vindication of Nature.*

I take it that Dr. Bonney is inclined to attribute a part of the blame to a faulty surgical technique on the part of doctors and midwives, and partly to the difficulty of sterilising the "area of operation," owing to the position of the vagina. He considers this to have been a blunder of Nature. If so, she has persisted in repeating it in a very wilful way almost throughout the mammalia. And, as if to emphasise her cynical disregard for the end of the genital canal, she has gone out of her way further to outrage surgical propriety by causing the sexually mature woman to produce an abundant growth of coarse hair almost completely encircling the vulva, and practically incapable of sterilisation. Now, the first duty of Nature is to preserve the race, and to do so she would scarcely be furthering her ends by introducing two death-traps in close proximity to the vagina.

I have no doubt that, in determining the plan of the human body, Nature thought of healthy bodies; a physiological process for delivery; and the practice of sexual intercourse merely for the propagation of the species, and not as a pastime. As a determining factor in sepsis at the time of labour, provided there has been no interference and no examination on the part of the medical man or midwife, I am of opinion that the "external" area of operation—viz., vulva and perineum—plays an insignificant part. For some excellent observations on this point I would refer readers to Dr. Routh's remarks at the reading of Dr. Bonney's paper.<sup>2</sup>

I do not wish it to be understood that I minimise the importance of sterilising this area as far as possible. But I believe that the real danger zone begins inside the vulva and increases in danger the nearer we approach the placental site. If the presenting part could reach the perineum through a sterile canal I do not think the external area of operation would be a serious menace to the patient. It is precisely on this external area that most of the surgical care has been lavished with such disappointing results; while the sterility or otherwise of the far more dangerous zone from within the vulva to the placental site—the real operation area—has been passed over in silence and that area assumed to be surgically clean. I am of opinion that the reason why there is such a large amount of sepsis still rampant in parturition is that the woman begins her labour with the vaginal canal, and sometimes the uterine canal, surgically unclean.

#### *Some Personal Reminiscences.*

Before I adduce the reasons which lead me to hold this view and put forward the well-known clinical fact that proves it conclusively, I will recall the conditions under

<sup>1</sup> THE LANCET, 1919, i., 775.

<sup>2</sup> THE LANCET, 1919, i., 796.

which midwifery was practised when I was a student, so as to show that, in spite of the uncleanness of the patients and the appalling conditions under which the majority of them lived, our results, though not quite so good as at the present day, were not so many points behind. It will help to show that, in spite of the vast improvements in housing and external cleanliness of the patient, and the scrupulous care that the doctor now takes to make himself and keep himself surgically clean during the conduct of labour, we have not succeeded in abolishing sepsis, but only in reducing it moderately. Such improvements apparently do not give the complete key to the conquest of puerperal sepsis.

Just 36 years ago I attended my first case of labour, in a mews off Gower-street. Students carried a midwifery bag, and in it were about half a dozen bottles, containing ergot, opium, chloral, sp. am. aromat., pure liquid carbolic acid, and perchloride of iron. A pot of carbolised vaseline, a Higginson's syringe, a perineum needle, and silver wire completed the equipment. Our district included some of the worst slums in London, and only those who lived and worked in them at that time can form any idea of what they were like.

The patient was prepared for the labour by having her clothes removed above the waist and her nightdress slipped on and tied up below the arms. Below the waist she very often retained her dress and petticoat. The bedspread consisted of an old blanket folded on brown paper, and the baby was usually wrapped in a petticoat when it arrived. Before examining the patient we removed our coats, washed our hands, and then rinsed them in 1 in 40 carbolic. The finger was anointed either with carbolised vaseline or with carbolic oil. The perineum and vulva were never cleansed before examination. The patient, as a rule, perambulated the room until the head came on to the perineum. Dress and petticoat were then loosened from the waist, and she got on to the bed. The dress and petticoat were drawn out of the way and the delivery took place. After the placenta had been expressed the nurse washed up the patient, and the soiled garments were pulled off. Those were the days of douches; and usually an antiseptic douche was given before we left. As a rule, the patient had douches for the first few days after labour.

#### *A Puzzling Result.*

Worse conditions for the patient can hardly be imagined; and the medical attendant was certainly neither aseptic nor rigorously antiseptic in his methods. In spite of this, no case of puerperal septicaemia occurred amongst the cases of the six men "on the list" for the month; nor did any case occur during my tenure of office as obstetric assistant. Of what we used to call sapraemia we had an abundance. The majority got well with vaginal douches, while a few required intra-uterine irrigation. Of deaths from puerperal sepsis, I am certain there were none, either while I was on the student midwifery list, or when I was in charge of the extern midwifery department. Of ophthalmia, we had plenty of examples; for we did not, at that time, wash out the eyes immediately after birth nor instil anything into them.

This is a puzzling result, if puerperal sepsis is invariably carried to the patient either by doctor or midwife, through carelessness in asepsis or antiseptics, or contracted through an uncleanly environment. These women ought to have died like flies, but they did not! They all made excellent recoveries. Far be it from me to underrate the urgent importance of surgical cleanliness for the successful conduct of labour and the safety of the patient. I only wish to throw up into relief the fact that it is precisely these conditions which have undergone such steady and vast improvement during the last 30 years with such disappointing results. They quite patently do not give the complete answer to the question that we are trying to solve; and we must therefore look around for some other clue. Dr. Bonney himself refers to the disappointment of the high hopes that were raised upon the introduction of trained midwives into obstetric practice. Some slight reduction of the mortality rate from sepsis followed; but once more the old experience reasserted itself, and the decline has not continued.

#### *Condition of Maternal Passages.*

Why has it come to a standstill? Why does sepsis continue to claim its yearly toll of victims amongst parturient women? The reason, I believe, is that the

maternal passage—the "internal area of operation"—nearly always contains the germs of sepsis within itself, at the time of labour. The route along which the fetus will have to travel, before it reaches the world, is practically never sterile.

On what do I base this assumption? *Simply on the notorious clinical fact of the prevalence of ophthalmia and conjunctivitis among children, within the first week of birth.*

We have succeeded to a large extent in suppressing the evidence of the existence of the infection by immediately washing out the baby's eyes with an antiseptic; but that does not alter the fact that the infection is there all the same in the maternal passage, and would have claimed its victim if we had not promptly intervened and destroyed it. Only let the nurse be careless in performing this duty and we shall not long be left in doubt about the reality of its existence.

Some dissentient may say: "What proof is there that this also is not an extraneous infection carried into the mother?" The proof consists in the fact that it may, and does, occur when there has been no interference in labour; and also, that the organism which produces the most virulent type of infection is the gonococcus. Most medical men would repudiate the suggestion that they possessed such a frequent and intimate association with this unpleasant invader as this hypothesis demands.

Now, what are the organisms that produce puerperal sepsis? They are varieties of streptococci, staphylococci, gonococci, and, as Dr. Bonney claims, also *Bacillus coli*.

What organisms cause ophthalmia? We know that the most virulent infection is due to the gonococcus, in which the conjunctival sacs become converted into bags of pus and sight is imperilled, unless the infection is promptly and vigorously dealt with. But not all cases of conjunctival infection after birth are due to this destructive organism. Everybody knows that there are all gradations of conjunctival inflammation after birth, varying from slight redness of the conjunctiva or inflammation with a minute drop of pus at the inner canthus occasionally during the day; or congestion, with thin muco-purulent discharge from the lids; or cases with a very small amount of discharge that dries on the ciliary margins and forms a powdery deposit. These cases are not ophthalmia neonatorum, but they are evidences of conjunctival infection by organisms in the vagina. Streptococci, staphylococci, and *Bacillus coli* may all produce conjunctivitis.

#### *How the Infection is Carried.*

Now, supposing that all these organisms do cause conjunctival infection of varying degree—and they most certainly can—what evidence is there that they are present in the vagina before labour? The evidence only requires that I shall produce proof either that they can be carried into the vagina by someone already infected, and acting as a carrier, or that they are transported either by the penis itself or from the area immediately adjacent to the vulva as it enters the genital canal for intercourse.

Of all venereal diseases gonorrhoea is the most prevalent, and it is one that in the majority of cases is incompletely cured. It is often associated with a secondary streptococcal infection; and it is now known that these organisms may persist for very long periods, either in the urethra or in the prostate or vesiculae, long after all external evidence of the disease has ceased and the patient believes himself cured. He is not well, and may infect his wife and child with the organisms of which he is a carrier. I do not know what proportion of the male population, at some period or other of their lives, suffer from gonorrhoea; but, judging from medical histories gleaned in the course of ordinary clinical examinations, it must be pretty heavy.

The transportation of streptococci, staphylococci, and *Bacillus coli* into the vagina is very easy. The skin of the penis and that of the vulva and female perineum are probably the most heavily infected cutaneous surfaces in the body. The penis is grasped with unwashed and soiled hands, and must receive many and various organisms, including streptococci, staphylococci, and *B. coli*. The organ is within trousers of varying age, which in most men have a flora of their own. When we turn to the lady conditions are present for supplying the organisms, as the average vulva and perineum must be suitable culture beds.

Should any be still doubtful as to the possibility of *Bacillus coli* and streptococci being introduced into the vagina from without they will do well to ponder also the question of their invasion of the vagina from within the body. With intestinal stasis and oral sepsis of common occurrence amongst women, the invasion of the bowel wall by these organisms is frequent, whence excursions to other and various parts of the body result. We know that both these organisms attack the kidney and bladder from the bowel, whence they are excreted in the urine and pass through the meatus urinarius. Once at the meatus, are they not within the portals of the vagina? What these organisms can accomplish via the urine they can also probably accomplish by direct attack on uterus and vagina in conditions of intestinal sepsis. In fact, I think the day may come when some portion of the cases of puerperal septicæmia may be traced either to intestinal stasis or oral sepsis.

#### *Evidence of Sepsis of the Vagina.*

There is no gainsaying the fact that sexual intercourse is practised by most people without the smallest attention to the cleanliness of the organs concerned. It is quite clear that in this way organisms must be introduced into the vagina, and as *Bacillus coli*, streptococci, and staphylococci abound in the organs they must be introduced into the vagina during intercourse. Add to this the frequency of latent gonorrhoeal and streptococcal infection of the male urethra, and the evidence of sepsis of the vagina becomes complete.

All this would be bad enough if it only occurred once during gestation. From inquiries made I am positive that the nauseous habit of sexual intercourse during pregnancy is the rule and not the exception, and that it is continued sometimes far on in gestation—at times, in fact, as long as mechanical conditions will allow. What would any surgeon say if he were asked to operate in an area that received the amount of soiling that is but the too common fate of the vagina? Yet this is what falls to the lot of the medical attendant at a confinement! I contend that, with our present methods of conducting labour, it is small wonder that disaster sometimes follows. The marvel is that accidents are not more frequent.

Some years ago I had a very conclusive proof of the capability of the uncleansed, but otherwise healthy, penis of causing puerperal sepsis. I attended a patient who had a perfectly normal labour. Until the morning of the eighth day recovery was uneventful and the temperature normal. On that day I was surprised to find the temperature between 100° and 101°. The vagina was washed out; on the ninth day the temperature was normal. On the tenth day it had again risen, and again the vagina was washed out. The temperature came down to normal, and remained so for two days, when it rose again. I was completely at a loss for an explanation of these fitful rises of temperature coming on after a period when the risk of puerperal sepsis was usually at an end. While debating these facts in my mind in the patient's bedroom I became aware that I was looking fixedly at a second pillow in line with her own. Without more ado I asked her if her husband had been occupying her bed since the end of the first week. I extorted a confession not only of that fact, but also that sexual intercourse had taken place on the nights preceding the morning rise of temperature. I had my little say and with it the trouble vanished.

#### *The Conduct of Labour.*

The problem, therefore, that the medical attendant has to solve is to deliver the child through a septic maternal passage, with a vulva and perineum also heavily infected. A portion of the problem has been already solved and has resulted in wiping off some part of the death-rate from sepsis, but part remains to answer still.

Concerning the surgical preparation of patient and attendant Dr. Bonney has dealt completely. One point as regards the toilet of the patient might be added—that the vulva should be shaved as for any other surgical operation. No doubt it would be a good deal opposed by patients, but I think it very important, in view of the impossibility of sterilising hair and the great danger of introducing septic organisms into the vagina, should interference be imperative. Should interference not be necessary this could be dispensed with.

What should be our attitude towards the vagina during the conduct of labour? Most certainly by every possible means we should avoid the necessity for internal examina-

tions. Parturition is a physiological process, and in quite 95 per cent. of cases the patient is capable of delivering herself. No doubt when Nature placed the vagina in front of the anus and surrounded the vulva with hair she hoped that this fact would be recognised, and that no unnecessary interference with the genital passage would become the fashion during the performance of this physiological act. Labour is a reflex act, and can be successfully conducted, not only without medical assistance, but also independently of the volition of the patient. Several cases are on record where pregnant women with complete transverse lesions of the cord have successfully accomplished it. Dr. Amand Routh reported such a case some years ago, and quite recently Dr. Drummond Robinson reported another.

#### *Avoidance of Internal Examinations.*

It is well known that women who have delivered themselves before the arrival of the medical attendant very rarely come to any harm. This was in my mind when making the assertion above that—provided there had been no interference—the perineum and vulva play but a small part in the causation of sepsis. The rule in the conduct of labour ought to be to avoid interfering with the genital passage wherever possible. It matters not whether the perineum and vulva be made as far as possible aseptic, and the medical attendant's technique be also rigorously aseptic, if he is going to conduct the labour by frequent examinations carried up as far as the cervix, through a vagina which, in the majority of cases, is contaminated with a variety of organisms. The perfectly aseptic gloved finger, if the vagina is septic, is capable of carrying up organisms from its walls, and smearing them on the inside of the cervix, and thus bringing them within reach of the most dangerous zone of the operation area—the placental site. If my contention is correct that conjunctival infection of the child is proof of sepsis of the maternal passage, then it becomes evident that to introduce even an aseptic finger into the vagina and carry it up to the inside of the cervix is fraught with considerable risk and should only be done if unavoidable.

The anxiety in the minds of medical men as to the state of the os is deep-rooted and genuine; and no wonder, since from hospital days they have always been exhorted to pay attention to it, and examine its size, consistence, dilatibility, &c., when called to a case of labour. I have known this anxiety spread even to a patient, who informed me on entering the room that I should find "the boss rigid"! After looking at the anus and perineum, I was able to assure her that this time the "'oss was a'doin' is best," and she need not worry. I know nothing of the routine now followed by lying-in hospitals during the course of labour; but I suspect that no inconsiderable part of their success in reducing sepsis is due, not merely to rigorous asepsis of patient and attendant, but also to the avoidance of internal examinations.

As far back as 1885, when I was a resident student at the Rotunda Hospital, Dublin, no patient was allowed to be examined more than once during the course of labour; and then only after thorough preparation of hands and forearms with soap and water and nailbrush, followed by soaking the hands in perchloride of mercury solution for three minutes. I have no doubt our patients on the midwifery list, when we were students, escaped septicæmia because they usually summoned us late in the course of labour, when the head or presenting part was in the middle or lower part of the cavity of the pelvis and fairly through the os; when danger of inoculating the cervix by examination was over; or, frequently, the child was born before our arrival. It was also the time of douches; and usually the vagina was washed out after labour.

#### *Nature's Method of Sterilising the Vagina.*

I have tried to show the undesirability of vaginal examinations during labour, on account of the undeniable fact of sepsis in the maternal passage: as evidenced by conjunctival infection in the newly-born child. It can be shown also that, in making such examinations, we are reversing and largely annulling the methods that nature brings into play to sterilise the vagina and wash out intruding organisms.

One of the earliest changes in the uterus, on conception, is oedema of the cervix, which steadily progresses throughout gestation. I do not think this phenomenon is the result of pressure, because it starts almost with impregnation. What-

ever its cause, my opinion is that it subserves a purpose over and above that of increasing the dilatibility of the cervix. With the progress of the presenting part the cervix becomes gradually dilated and subjected to an increasing pressure. As a result vessels are ruptured, and tears small or large occur. The torn vessels are sealed, and from them exudes a copious flow of serum mixed with extravasated blood. The purpose of this serous exudation is, doubtless, physiological, and it is in all probability bactericidal, resembling the flow of lymph after wounds in other parts. Its rôle is probably partly to cleanse the vagina and partly bactericidal to retained organisms. It is tempting to suggest that, when impregnation occurs, there is a local retention of salt in the tissues of the cervix, which attracts fluid to itself and stores up a lymphagogue, to be put to practical use during labour.

While all this is a physiological process and wholly beneficial to the patient, it becomes far otherwise if vaginal examinations are made the rule in labour. Instead of a protection, it may be a menace to life. Granting that the vagina must, in most cases, be a canal harbouring noxious organisms at the time of labour, the danger of introducing a finger and carrying it up to a wounded cervix is apparent. If the finger is also introduced inside the cervix and swept round between the bag of membranes and the uterine wall, we may be simply implanting colonies of organisms on the uterine wall, and with nothing between them and the uterine sinuses. Now, the organisms which we have shown reason to believe most likely to gain entrance to the vaginal canal are gonococci, streptococci, staphylococci, and *Bacillus coli*. Of these four the one with the power of causing a specific effect is the gonococcus; but it shares with the others the ability of producing non-specific inflammations in other parts of the body. All of them may enter the blood stream, and, by causing bacteriæmia, set up inflammatory foci in various tissues. How careful, then, ought we to be to avoid bringing them into contact with wounded surfaces. Of all possible channels for the entry of organisms vascular lymphatics are easily the first.

#### *Some Guiding Rules.*

If the facts that I have endeavoured to make plain are true, what should be our method in the conduct of a case of pregnancy and labour? In my opinion it should be as follows:—

1. The patient should have a general physical examination, and the state of her health should be accurately gauged.

2. At the time of examination the urine should be examined, and the examination should be repeated at intervals of two months.

3. The external diameters and circumference of the pelvis should be taken; also indications of marked lateral curvature, old angular curvature, and past rickets should be looked for.

4. A careful abdominal examination should be made between the seventh and eighth months, or later if the pelvic measurements are normal, to ascertain the position of uterus and contained fetus. By training this method yields accurate results, and the presentation can be determined with practical certainty. The position of the foetal heart sounds in this connexion is of great importance and should be always noted.

5. If the patient is a multipara the history of previous confinements should be obtained.

Armed with this knowledge it will be possible to conduct the vast majority of labour cases without vaginal examination.

Up to the present it has been too much the fashion to recognise only external sources of infection and the methods by which they may gain entrance to the maternal passages during labour. The equally important fact that vaginal sepsis is already present when labour starts, as proved by conjunctival infection in the newly-born child, has been waived as absurd and this important clinical fact not rated at its proper significance and gravity. A few will grudgingly admit that on rare occasions autoinfection may occur. Not on rare occasions, I submit, but on every occasion, should the possibility be held in mind, and a septic canal be as seldom interfered with as the safety of the patient will allow.

Dr. William Ewart Gye announces that he has formally relinquished the surname of Bullock and assumed the name of Gye. His address remains as in the Medical Register, 1919.

## KINEPLASTIC AMPUTATIONS.

BY M. FITZMAURICE-KELLY, F.R.C.S. ENG.,

ACTING MAJOR, R.A.M.C.

THE object of this paper, which is a preliminary communication, is to present briefly the methods employed, and the results obtained, in a series of kineplastic amputations recently performed at the Pavilion Hospital, Brighton. The subject has, so far as I am aware, found a very small place hitherto in British—or French—surgical literature and practice; but the pitiable plight of men who have lost an arm seems to call for a very thorough trial of any method which holds out the hope of better things, while the results so far obtained justify the expectation that the method may be found of great value.

#### *Selected Cases.*

The cases selected for trial were, in the first instance, those with amputation stumps which were unsuitable for the fitting of an artificial limb; short forearm stumps—two to three inches below the elbow, measured from the tip of the olecranon process—or stumps a little longer, with partial and incurable limitation of movement in the elbow-joint. Later, in longer forearm stumps, tunnelisation of the muscles was tried, and finally amputations through the elbow- and wrist-joints were operated upon by a method arising out of previous experience. It is not my present intention to lay down definite indications for kineplastic amputation; I think it may fairly be claimed that the cases so far selected had nothing to lose by the operation and much to gain in the event of success. And there now seems ground for hope that the advantages will be great enough to justify the sacrifice in length in stumps hitherto rated as useful.

#### *Literature.*

In starting this series, which at the time of writing includes 13 cases operated on in the last eight weeks, I found considerable difficulty in getting much light and leading from the literature at my command. By far the most valuable paper was Vanghetti's<sup>1</sup> on General Principles; Pellegrini's<sup>2</sup> contribution contained useful suggestions on the technique of tunnelisation, while critical abstracts from German surgical literature in the *Medical Supplements* issued by the Medical Research Committee gave valuable hints, chiefly on methods which it seemed desirable to avoid. For the rest—and I imagine it will be the case with most surgeons—I had to devise my own technique and modify it as the particular cases demanded.

#### *Plastic Motors: Technique.*

The forms of plastic motors attempted have been two: club-shaped motors, built up of muscles with their bony insertion, or an adventitious bony attachment, and loop motors, made by constructing a canal or tunnel lined with skin and surrounded with muscle or tendons. Of the 13 cases operated on, in 4 club-shaped motors alone have been made (two each in 3 cases and three in the fourth); in 3 cases skin tunnels only have been constructed (one in each case), while in the remaining 6 cases, two club-shaped motors and one tunnel have been made in each case. In describing the technique, it will be simplest to deal first with the tunnelisation method, and then to give the various methods used to make the club motors.

*Loop motors.*—In making the skin canals, the double-pedicle method suggested by Pellegrini has, in the main, been followed. The length of the canal required will vary according as muscle or tendon is to be used for the loop; but there is an advantage in making it short and wide, as the blood- and nerve-supply is better, and the tendency to excoriation less. Two incisions are made of the length required, parallel with one another, and 2 inches apart. From the ends of each cut oblique diverging incisions are made in a proximal direction. The lower end of the area so marked out is dissected up, with the subcutaneous tissue down to the deep fascia, and the upper edge is freed until the skin can be rolled up to form a canal by union of the edges of the two original incisions. These edges are then united with a subcuticular suture of fine silkworm gut and reinforced with a few points of catgut in the subcutaneous tissue. The subcuticular suture gives accurate apposition and is easily removed. The canal being thus formed, the deep fascia is opened

<sup>1</sup> Archives Médicales Belges, June, 1913, p. 653.

<sup>2</sup> Ibid., p. 675.

above and below, the muscle or tendons which it is proposed to place superficial to it selected, brought over, and sutured to the deeper parts on the distal side of the canal. It is important that both the superficial and deep tendons or muscles should be liberated from attachments or adhesions below and the canal itself freed from attachment to the deep fascia, in order to obtain the greatest possible freedom of movement and the widest excursion. The motor so formed is then covered in by a plastic operation, gliding flaps from above and below, and a piece of gauze packing passed through the canal.

*Club motors.*—The making of the club motors is more difficult, and can perhaps be most easily described as done at the elbow, where powerful muscles with their bony insertions are available. In a typical case, where it is intended to use the triceps and the brachialis anticus, the operation is best performed from behind forwards, as this mode of access keeps the structures it is intended to preserve out of harm's way until the latest possible moment. A tourniquet is applied, and a posterior flap is first marked out with its base equal to half the diameter of the limb opposite the condyles, and including all the available skin on the back of the stump. The incisions will probably need to be prolonged upwards at a later stage. This flap is dissected back to the base of the olecranon process; the latter is sawn through and the joint so opened from behind. The lateral attachments of the olecranon are severed, the posterior capsule divided, and the triceps dissected up from the back of the humerus to a distance of about  $3\frac{1}{2}$  inches above the condyles. The skin covering the superficial aspect of the muscle is left undisturbed. The muscle and its attachment, thus isolated, are wrapped in gauze. The coronoid process is then detached by a saw-cut carried downwards and forwards from the interior of the joint, and the brachialis anticus carefully isolated from the structures on either side. The biceps tendon, if it has not already been utilised to build another motor, is then divided, and the remaining structures—supinator longus and the muscles arising from the condyles—dissected away, all the skin on the anterior surface of the stump being preserved. The brachialis anticus is then separated from the humerus to the same level as the triceps and the humerus then sawn across. The tourniquet is removed, all bleeding vessels tied, and all nerves shortened. The biceps, if available, is stitched to the brachialis anticus, and the two motors thus formed are clothed with skin. In doing this two points need careful attention: one is to place the skin stitches very accurately round the neck of the motor, where pressure will ultimately be taken, and the other is to fix the bony insertion firmly to the skin to prevent retraction. The best method of doing this is by an anchor stitch of stout silkworm gut, which transfixes the tendon close to its insertion and the connective tissue on either side of the bone; the two ends issue through the skin close to the apex of the motor, about three-quarters of an inch apart, and are tied on a piece of drainage-tube threaded on to one end. These should not be tied tightly and should be retained, if possible, for 10 or 12 days.

A certain amount of oozing is inevitable from the large wound involved in this operation; the method of drainage employed is by strands of silkworm gut. About six strands are knotted together, and three or four of these are passed in various directions, one from base to apex of each motor. These are removed after 48 hours, and the wound is not dressed again until the tenth day, when the stitches are removed.

#### *The Two Methods Combined.*

The methods above described—tunnelisation and club motors—have been combined in six of my cases.

First, a skin tunnel was made in front of the arm, just above the bend of the elbow. The biceps tendon was split after being divided low in the wound, and the superficial half brought in front of the tunnel and sutured to the deep part. Then motors of the club type were made of the triceps and brachialis anticus, the plastic operation to cover the canal being left to the end, when it was made easy by taking up the slack skin from the end of the stump. The object is to use the biceps as a supinator of the artificial hand, but none of the cases are sufficiently advanced yet for a definite opinion to be expressed as to whether the motor will develop sufficient power or independence of action to be effective, and in my most recent case I made a third club motor by turning up a U-shaped flap from the front of the elbow, detaching the tubercle of the radius and shortening the biceps tendon by folding it in a Z upon itself.

#### *Another Modification in Technique.*

Yet another modification in the technique, which seems full of promise and of very wide application.

In two cases, amputations through the elbow and wrist-joints respectively, the adventitious adhesions of the muscles were used to make club motors. In the first, pieces of the lower end of the humerus, with the cut ends of the

brachialis anticus and triceps still adherent to them, were bisected off the anterior and posterior surfaces of the end of the bone; the muscles were then dissected up as before, and the shaft sawn through at a higher level. In the latter, pieces of the lower end of the radius were similarly preserved with the flexors and extensors of the fingers attached, and the overlying skin undisturbed. Both healed well and show movement, but are not yet sound enough to take a load.

#### *Review of the Methods Adopted.*

Reviewing the cases, as far as I have gone, I am not favourably impressed with the possibilities of the skin tunnels. Others who have used the method—notably Sauerbruch, Drüner, and other German surgeons, using a technique similar to Rochet's urethroplasty—have had trouble from excoriation of the canals, and though this risk is diminished by making short wide tunnels with a good blood- and nerve-supply, it still exists. More important is their limited range and limited power, as compared with the club motors, and I am inclined to doubt whether they will take a permanent place in kineplastic surgery.

On the other hand, there seems good reason to hope much from the club motors, especially when multiple, and including a pair of antagonistic action. The motor being wholly exteriorised, the covering remains healthy and able to bear pressure, and about the power developed there is, happily, no doubt. That is, after all, as one would have guessed, as the preservation of the bony insertion of a muscle means the concentration of the force it exerts in one available point. And, as far as I have tested them, they bear pressure well, even within a few weeks of the operation. One of my early cases is now on a temporary training apparatus made out of a Thomas arm-splint, working the muscles against an elastic resistance, and, tested with a steelyard inserted in place of the indiarubber tubing, he registered 15 lb. with one motor and 21 lb. with the other at the first attempt. The arm still appears quite wasted, and is, I am sure, capable of much greater development. And several of the later cases are much more promising—the motors have been made longer, and I propose, in one or two of the early cases, to remove an inch more of the humerus to increase the range of the motors.

The apparatus used to attach the motors is a metal collar with hinge and screw adjustment, similar to Putti's. They are made for me in the temporary limb department of the Pavilion Hospital, and coated with vulcanite by a dental mechanic. I have found that it is best that they should not fit accurately, as if they do marked congestion of the motor is caused, and I am now having them made circular for motors which are oval in section, and vice versa. The motor then keeps its colour perfectly, and the patient is more comfortable.

All the cases in the present series are arm amputations, but though the much more satisfactory prostheses available make the problem less urgent in the lower limb, I think there are certain cases in which it is worth while. I refer to the group of short and unsatisfactory stumps below the knee. Some of these, owing to deficient movement, cannot be fitted with a limb; others with very short stumps, after trying a kneeling leg and finding it unsatisfactory, return for re-amputation above the knee. In some of these cases, which I now have under my care, I propose to build motors of the quadriceps and hamstrings, so as to give the patient voluntary control of the knee-joint. It should be easier to do, and easier to fit, than the operations in the region of the elbow.

I regret, and apologise for, the incomplete state in which this work is presented, but judging from the difficulty in coming at any records in English surgical literature, the number of cases on which these observations are based constitutes an exceptional experience. And already I feel very strongly that the club-motor method—and especially its extension by the use of adventitious bony attachments—is that which holds out hope for the future, and it is in the hope that English surgeons will give the method a more extended trial that I present my conclusions in their present form. I hope, later in the year, to bring forward a more complete record, and to show cases.

I have to acknowledge my deep indebtedness to Mr. Muirhead Little, on whose representations this work was undertaken, and whose advice and help in the selection of cases, and in unearthing literature, have been invaluable. Also, to my colleagues at the Pavilion Hospital, Brighton, for much encouragement and help.

OBSERVATIONS ON  
LENGTHENING OF AMPUTATION STUMPS.By W. E. GALLIE, M.B., F.R.C.S.,  
MAJOR, CANADIAN ARMY MEDICAL CORPS.

AMPUTATIONS in which the femur is sectioned less than three inches below the lesser trochanter are most unsatisfactory for fitting with artificial legs. The various suggestions made for overcoming the difficulties have not been very successful. As far as I know, no surgeon has hitherto attempted to lengthen the stump. The following case shows that such a procedure is possible.

*Account of Case.*

Pte. B. was admitted to the Granville Canadian Special Hospital, Buxton, on April 15th, 1918, with amputation of thigh at about junction of upper and middle thirds. The amputation had been performed with equal anterior and posterior flaps; wound had healed, except in centre, where a discharging sinus led to dead bone. On May 3rd, 1918, operation for the osteomyelitis; the terminal inch of the femur was necrotic and had to be removed, thus the bone extended only two and a quarter inches below lesser trochanter. The flaps were sutured back in position; wound healed in two months. Patient was then fitted with a temporary artificial limb, but the femur was so short that when he flexed the hip the end of the bone slipped forward over the top of the socket. We were confronted with the necessity of fitting him with the tilting-table leg or of lengthening the femur.

On Feb. 27th, 1919, he was operated upon again. The flaps were reflected as before and the incision continued up the outer side of the thigh as far as the great trochanter and deepened until the bone was exposed. The muscles were then reflected until the outer half of the femur was laid bare. With an osteotome applied in the sagittal plane a half of the terminal three and a half inches of the shaft of the bone was cut free. This piece of bone was slid downwards so as to lengthen the femur by two and a half inches, and was then fastened by two long screws of beef-bone.<sup>1</sup> The flaps were then dissected up sufficiently far to allow them to be drawn down and closed over the end of the bone. The wound healed by primary union, except for a hematoma, which opened spontaneously and disappeared without infection, otherwise recovery uneventful.

Two months later the fragments were solidly united and the patient commenced active exercise of the stump to increase the density of the bone. He is now wearing the ordinary artificial limb and has a very satisfactory stump.

*Remarks.*

This case resulted in several observations. Owing to osteoporosis the fixation was none too good. As solid fixation of the fragments is imperative, it would be wise to convert the screws into bolts by small nuts made of beef-bone. Heavy silver wire, or the brass ribbon used by Putti, or even metal bolts would serve, but the beef-bone has the advantage<sup>2</sup> of uniting rapidly to the living bone and of undergoing absorption and replacement, as does an ordinary autogenous graft.

The extensive splitting of the bone led to rather profuse hemorrhage. This could be avoided by substituting for the method described an ordinary inlay bone-graft or a graft driven into the medullary cavity. We have one case of amputation of the leg in which the fibula will be used after splitting it into two halves to allow the endosteal osteoblasts to be bathed in lymph, either as an inlay or as a medullary graft, lengthening the stump an inch and a quarter. In this case the flaps are sufficiently long and the fibula is much longer than the tibia which was sectioned just below the tubercle.

The bone in the stump may be too short to allow an operation as such described, and it may not be wise to remove a graft from the other leg. In such a case a suitable graft might be obtained from a recently amputated limb. We have satisfied ourselves that bone transplanted from one animal to another of the same species—at any rate, in dogs—retains vitality in the same sense as does an ordinary autogenous graft—that is, those cells which are exposed on the surfaces to a supply of lymph survive and proliferate, and ultimately accomplish the absorption and replacement of the graft. It would be well, in transplanting bone from another patient or from a recently

amputated limb, to make sure that the cells of the one patient are capable of living in the lymph of the other, as indicated by the testing of their bloods for hæmolytic and agglutination. A recent paper by Masson indicates that Thiersch skin-grafts from a donor whose blood is not compatible with that of the patient do not live; if the bloods are compatible the transplantation is successful.

Up to now the operation described appears successful, but failure is still possible owing to absorption of the graft. Only time can show, and this paper is but a preliminary report. There is reason to believe, however, that such grafts will not disappear. When autogenous bone is transplanted into the muscles of the back in animals the bone ultimately disappears. But if such grafts are so placed that they have work to perform, as when used to bridge gaps in the long bones, they ultimately increase in thickness until the bone is restored to approximately its normal outline. Evidently the fate of such transplants is dependent upon the work performed. Up to the present the X ray shows no evidence of disappearance of the graft, and a mass of new bone has restored the normal thickness of the shaft where the graft was removed, and has also increased the thickness of the graft itself.

Among our wounded are many who could have such an operation done, for we have seen men passing through this hospital who had very short bones in their stumps and yet ample flaps of skin to allow bone-lengthening. It has been the practice to remove these redundant flaps by re-amputation. Again, if a successful lengthening of the bone can be looked forward to, the method of primary amputation, when short bones are inevitable, should be changed. The skin-flaps should be left very long, so that later sufficient skin will be available to cover the graft properly. This would also apply in civil practice.

A CASE OF  
CARCINOMA OF THE PELVIC COLON

TREATED BY EXCISION AND ANASTOMOSIS.

By CLAUDE FRANKAU, C.B.E., D.S.O., F.R.C.S. ENG.,  
SENIOR ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL.

THE following case of apparent cure following excision of a carcinomatous stricture of the pelvic colon may be of interest inasmuch as there is no evidence of recurrence after six years.

*The Case Described.*

A man, aged 47, was admitted into St. George's Hospital on July 4th, 1913, for intestinal obstruction. He had apparently been absolutely well until four days previously; he then noticed a certain amount of colicky pain and had absolute constipation, which was not relieved by drugs or enemata. On examination he did not look ill. Pulse 88, temperature normal. Tongue slightly furred. The abdomen was enormously distended and was tympanitic all over. Rectal examination was negative. An attempt was made by means of further enemata to open the bowels but without result, and it was clear that the obstruction was complete. The same evening I opened the abdomen in the middle line; all the intestines were greatly distended, the cæcum being enormous and showing commencing splitting of the serous coat. The cause of the obstruction was an annular stricture of the pelvic colon just above the pelvic floor; the growth was movable and there appeared to be a prospect of excising it with good results if the man recovered from the intestinal distension. The mid-line incision was therefore closed and a second muscle-splitting incision made over the cæcum; as soon as the peritoneum had been incised the cæcum bulged out and burst partly externally and partly intraperitoneally; a Paul's tube was sewn into the tear in the cæcum and the peritoneal cavity was cleansed locally as far as possible. In spite of the enormous distension present before the operation and the peritoneal infection he rapidly improved, so that three weeks later a second laparotomy was performed with the idea of excising the growth. On examination the growth, which resembled a tight ligature round the gut, was found to be quite freely movable, and there appeared to be no glandular involvement. It was situated so near the pelvic floor that the feasibility of an anastomosis seemed doubtful. However, after clamping and dividing the gut above the growth and dividing the mesentery, it was found possible to draw the growth and the distal part of the gut up and divide it about three-quarters of an inch above the pelvic floor. An end-to-end anastomosis

<sup>1</sup> Canadian Medical Journal of Medicine and Surgery, May, 1916.<sup>2</sup> Journal A.M.A., April 20th, 1918, lxx., 1134-40.

was then performed by means of a double layer of interrupted stitches. This proved to be a matter of very great difficulty and could only be effected by the use of the high Trendelenburg position and after partial division of the left rectus abdominis muscle to allow of easier access. Owing to the likelihood of leakage from the suture line, a rubber drain was left in for the first three days. Enemata were commenced on the eighth day after operation, and small actions were obtained every other day. On the twenty-fourth day after the excision the caecostomy was closed by operation, and normal actions of the bowels followed. The growth proved to be a columnar-celled carcinoma; some small glands in the mesentery were not involved.

*No Evidence of Recurrence.*

I saw the patient every few months up to the summer of 1914. Owing to the war I was unable to see him again until May, 1919, when he was in very good health and had no intestinal symptoms of any sort. Abdominal examination was negative, and there was no local evidence of recurrence.

In this case the absence of prodromal symptoms before the obstruction became absolute is remarkable, and the man must be regarded as extremely fortunate to have survived the enormous distension found at the first operation and the effects of the rupture of the caecum.

# A NOTE ON SEGMENTAL HYPERALGESIA IN MALARIA.

By D. W. CARMALT JONES, M.D., F.R.C.P.,  
LATE TEMPORARY COLONEL, A.M.S., AND CONSULTING PHYSICIAN, E.E.F.

In the course of 1918 I made a series of observations on segmental hyperalgesia in trench fever, which were embodied in a paper published in THE LANCET.<sup>1</sup> The substance of them was briefly as follows:—

If a series of light pin-pricks are made on the skin in a direction which crosses a large number of areas of segmental nerve distribution, it will be found in patients suffering from trench fever that three groups of areas are unusually sensitive, particularly as to their borders. The groups are an upper one containing the eighth cervical and first dorsal areas, a middle one containing the seventh dorsal area, and a lower one containing all the lumbar areas. The areas are not found in every case, and in positive cases only parts of these groups may be hyperalgesic, but something of the kind is present in the great majority.

I noted in this paper that in 18 cases of malaria which had been examined similar areas were found. I have since had the opportunity of examining patients suffering from malaria in very large numbers, both at a camp in France, where patients were treated who had been infected in other theatres of war, and also in Egypt and Palestine, where malaria was incomparably the highest cause of sickness during my service there. I was able to find the same areas of hyperalgesia in the great majority of cases, and they differ in no important particular from those found in trench fever, and such minor variations as were present are stated below.

*Analysis of Results.*

The following is an analysis of the results found in 120 cases examined consecutively for this sign.

Cases examined, 120. Positive 83 (70 per cent.). Negative 37 (30 per cent.). This is a lower incidence than in trench fever, where I found only five negative in 73 cases, but malaria is capable of far more certain recognition, and I came to rely on the presence of these areas for the differential diagnosis of trench fever.

The areas found hyperalgesic in the malarial cases were these:

Upper group	... { C. 8 ... .. 9 }	44 = 50% of positive cases.
	... { D. 1 ... .. 35 }	
Middle group	... { D. 7 or 8 ... .. 83 }	100% " "
	... { L. 1, 2, 3, 4, 5 ... .. 42 }	49 = 59% " "
	... { L. (incomplete) 7 }	
Full distribution	C. 8, D. 1; D. 7; L. 1, 2, 3, 4, 5, 8	cases = 10% of positive cases.

It was remarked that these areas could never be demonstrated while a rigor was in progress.

In 68 positive cases of trench fever the results were these:

Upper group	... 39 = 57%	Lower group	... 67 = 99%
Middle group	... 68 = 100%	Full distribution	24 = 35%

The only differences are the more frequent escape of the

lumbar in malaria, and the consequent reduction in the number of cases of complete distribution.

The middle group shows a few minor differences; in trench fever it is rare to find anything but D. 7 or D. 7 and 8 involved, but in the malarial cases D. 6 was found once, D. 8 17 times, and D. 9 once, also in nine cases the hyperalgesia was unilateral, which was hardly ever found in trench fever.

*Conclusion.*

The similarity between the signs as found in the two disorders remains very striking and adds one more to the many likenesses between them: one being mosquito-borne and the other louse-borne; one admittedly protozoal, and the latter probably so from its cyclic character and its capacity for lying latent; both associated with enlargement of the spleen.

It is necessary, however, for either disease to be excluded before the presence of such segmental hyperalgesia can be allowed weight in the diagnosis of the other.

# PARATYPHOID INFECTIONS OF THE PLEURA.

By J. HILL ABRAM, F.R.C.P.,  
HONORARY PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL; LATELY ACTING  
PHYSICIAN, NORTHERN HOSPITAL, LIVERPOOL;  
AND

ERNEST GLYNN, F.R.C.P.,  
PROFESSOR OF PATHOLOGY, UNIVERSITY OF LIVERPOOL;  
CAPTAIN, R.A.M.C.T.

(From the Thompson Yates Laboratory.)

PNEUMONIA, and especially bronchitis, is not an uncommon complication of paratyphoid fever<sup>1</sup>; but sero-fibrinous or purulent pleurisy due to infection with the paratyphoid bacilli is apparently so rare that the following cases deserve recording.

CASE 1.—F. L., a man aged 38, was admitted to the David Lewis Northern Hospital, Liverpool, on Feb. 12th, 1918, after being crushed between a wagon and a wall. The left side was strapped. During the 11 days he was in the surgical ward he had some diarrhoea, and typhoid was suspected. He was then transferred to a medical ward with signs of consolidation at the left base. As the breath sounds were very feeble, although there was no displacement of the heart, a needle was inserted into the pleura and 5 c.cm. slightly turbid fluid were obtained.

On bacteriological examination a motile Gram-negative, indol-negative organism was present in pure culture, which gave the characteristic reactions of paratyphoid B in lactose, glucose, maltose, mannite, and saccharose. It agglutinated with the Lister Institute paratyphoid B serum 1—6500, but not with the paratyphoid A or typhoid serum.

The patient's serum agglutinated his own organism 1—1250, and the results with the Oxford standard emulsions were: typhoid—1—25, paratyphoid A—1—25, paratyphoid B + 1—1250. The fæces were not examined.

Throughout his stay in the medical ward the temperature never rose above 100·4° F., and the respirations above 30, but the pulse averaged about 100. Treated on general lines he made an uninterrupted recovery without any further operative treatment.

CASE 2.—M. W., a woman aged 24, was admitted to the David Lewis Northern Hospital, Liverpool, on July 22nd, 1918. She stated that three months previously she suffered from "influenza," and recently had pain in the left side. There were obvious signs of pleural effusion, her temperature was 104° F., pulse 124, respirations 44. On July 23rd 2½ pints of clear fluid were removed by aspiration. On August 1st the chest was again explored, and as pus was found the empyema was opened; the patient made an uninterrupted recovery. The fluid was examined after aspiration and twice subsequently when the chest had been opened. It always contained a streptococcus longus and a bacillus which gave the characteristic cultural tests of paratyphoid B, it agglutinated with the Oxford paratyphoid serum up to 1—40, titre 1—100.

The patient's serum agglutinated her own organism 1—96, and the results with the Oxford standard emulsions were: typhoid—1—25, paratyphoid A—1—25, paratyphoid B + 1—50. The fæces were examined with negative results.

*Cases Reported by Other Observers.*

Lenhartz (1910) published the first case of pleurisy in paratyphoid fever; here the effusion was serous and contained paratyphoid B bacilli in pure culture.

<sup>1</sup> An Address on Sensory Changes in the Diagnosis of Trench Fever, THE LANCET, Oct. 5th, 1918.

<sup>1</sup> Dawson and Whittington, 1916; Willcox, 1916; Hurst, 1917.

Costa and Clavelin (1911) described the case of a man who developed empyema due to paratyphoid B five weeks after the onset of the fever. They also mention two of serous effusion described by R. Schmidt and Sacquépée and Chevrel respectively—here the type of paratyphoid bacillus is not stated, but it is almost certainly B.

According to Schottmüller (1911) pleurisy is often met with in paratyphoid fever, and even when suppurating will clear up with repeated aspirations. He alludes to a case by Lorey where the effusion occurred during a "long-drawn-out" attack of paratyphoid B fever.

#### War Cases.

Several others have been recorded during the war, notably by the French authors.

Joltrain and Petitjean noted that during the 1915-16 epidemic of enteric in the French Army pleural complications were rare amongst the typhoid cases—viz., 2-4 per cent., but common amongst the paratyphoid cases—viz., 19 cases in 310—i.e., 6 per cent. In the latter pleurisy was purulent in 2 per cent., dry in 2 per cent., and sero-fibrinous in the rest. Paratyphoid B was isolated—apparently from the blood—in all the cases except one, where paratyphoid A was found. The pleurisy usually developed in cases of atypical or latent paratyphoid; it was sometimes the first symptom. The exudate in the sero-fibrinous cases contained a preponderance of lymphocytes and endothelial plates.

Jean Minet (1915) carefully described 8 cases of paratyphoid infection with complications in the "lung and pleura"; the complication was usually bronchitis. In two, viz., Nos. 6 and 7, there were definite signs of effusion. In No. 7, some drops of citron colour liquid removed by aspiration were sterile. In No. 8 paratyphoid B bacilli were isolated from the sputum and from the blood.

Florenzano (1916) reports a case of pleurisy with effusion of clear yellow fluid which gave a positive agglutination to paratyphoid B. The patient later developed symptoms of typhoid.

Two other observers have noted paratyphoid A infections. (1) Giroux (1915). Here the patient developed pleurisy in the third week of paratyphoid; the fluid was first serous, then hæmorrhagic, and finally purulent; the bacilli were isolated from the empyema, but two blood cultures were negative. (2) Weeks (1916). Here the patient, who was also a soldier, "had diarrhoea for a fortnight and was apparently well, when two weeks before admission to hospital he was seized with acute pain in the back." He subsequently developed empyema, which was opened, and finally recovered.

A case of pleurisy due to an "inagglutinable paratyphoid B" bacillus is worth alluding to.

Pte. W. received a gunshot wound in the region of the left rib on Nov. 17th, 1916, after which he lay for 24 hours in water. He was transferred to Toxteth Military Hospital, Liverpool, under the care of Captain J. R. Logan. The bullet was removed at Toxteth in January, 1917; it had apparently damaged the pleura, but not the lung. An empyema developed, which was aspirated on three occasions in two months, after which he recovered. Each sample of pus contained in pure culture a persistently "inagglutinable paratyphoid B" organism; it did not absorb paratyphoid agglutinins; the patient's serum agglutinated it up to 1-128. The same organism was isolated from the urine once. Further particulars regarding it are given elsewhere.<sup>2</sup>

#### Civilian Cases.

In conclusion, it is noteworthy that both our cases of typical paratyphoid B pleurisy occurred in civilians.

During the years February, 1917, to February, 1919, the sera of about 40 civilian patients, excluding sailors, with enteric-like symptoms were tested in this laboratory with the Oxford standard emulsions. The patients were in the Liverpool Royal Infirmary and the Northern Hospital; none had been inoculated with T. or T.A.B. vaccine. Twenty—i.e., 8 men, 10 women, and 2 children—agglutinated typhoid only, the lowest titres being 1-25 one case, 1-50 two cases, while the rest ranged from 1-250 to 1-5000. On the other hand, five cases agglutinated paratyphoid B. only—viz., W., adult male + 1-50; M., adult male, hospital dispenser, + 1-1000; W., hoy, + 1-50; E., hoy, + 1-500; M., adult female + 1-25+. The rest were negative to all three emulsions. Including the two pleurisy cases, 27 patients gave some agglutination either to typhoid or paratyphoid.

Excluding the two cases with titres of + 1-25 (typhoid) and + 1-25+ (paratyphoid B), the clinical history and agglutination results indicate that 19 were almost certainly typhoid and six almost certainly paratyphoid B. These statistics are obviously based on too few cases to afford more than a very rough indication of incidence, but a proportion of approximately 1 of paratyphoid to 4 of typhoid is higher than most medical men or public health authorities would expect.

Nevertheless, there has undoubtedly been a relative increase in the number of cases of enteric<sup>3</sup> diagnosed as paratyphoid amongst the civilian population, since the outbreak of war. This increase is probably partly *real*, and due to the presence of soldiers or sailors with paratyphoid, most probably carriers who have escaped detection by the routine bacteriological examinations before discharge from hospital. The paratyphoid outbreak at Reading amongst civilians was probably due to infected soldiers (Donaldson, 1916). The increase is also partly *apparent* and due to improved serological and bacteriological technique, especially the former.

Dr. E. W. Hope, medical officer of health for the city of Liverpool, kindly informed us that during the years 1907-08, 929 civilians were notified as suffering from enteric or typhoid, and none from paratyphoid, while during 1917-18, 91 civilians were notified as suffering from enteric or typhoid and four from paratyphoid. Thus the number of paratyphoid cases notified in the whole city of Liverpool is, two, if not three, less in approximately the same period than those diagnosed serologically or bacteriologically in two hospitals where there were only 19 or 20 cases of typhoid. This discrepancy is undoubtedly explained by the fact that the medical man usually diagnoses his patient on clinical grounds only, and hastens to notify him as enteric or typhoid before a proper bacteriological investigation. If the patient is subsequently proved to be paratyphoid, the original notification is usually not corrected.

Thus the official figures of the relative number of typhoid and paratyphoid cases among civilians will be misleading until they are invariably controlled by the bacteriologist.

We are indebted to Mr. Hugh Smith for assistance in the bacteriological work.

For an interesting review of Typhoid Infections of the Pleura see a recent annotation in *THE LANCET*.

## SMALL-POX NOTES FOR PRACTITIONERS.

BY W. MCCONNELL WANKLYN, B.A. CANTAB.,  
M.R.C.S., L.R.C.P., D.P.H.,

AUTHOR OF "HOW TO DIAGNOSE SMALL-POX," "ILLUSTRATIVE CASES IN THE DIAGNOSIS OF SMALL-POX," "THE ADMINISTRATIVE CONTROL OF SMALL-POX," ETC.

It may be a service to colleagues in practice who have been unable to keep in touch with the subject to note how small-pox stands at present, and give some brief notes on diagnosis. A list of sources of further information is added.

This year there have been cases of small-pox in London, Liverpool, Bootle, Bebington, South Shields, Hartlepool, Middlesbrough, Lincoln, Wishech, Ilford, Darlington, Pontefract, Featherstone, Bracebridge, Bury St. Edmunds, Herefordshire, Amersham, Chorley Wood, Bishops Stortford, East Ham, Southampton, Weymouth, Jarrow, Barnard Castle, Hull, Derby, Plymouth, Cowes, Strood, Mitcham, Penge, Southend, Gravesend. There has been an unusual prevalence.

#### Previous Epidemics.

Small-pox was last widely prevalent in England about the year 1902, when there were about 8,000 cases in London. It

<sup>3</sup> "Enteric Fever.—Varieties: (a) Typhoid Fever; (b) Paratyphoid Fever." See 1916 edition *Nomenclature and Classification of Diseases*, Royal College of Physicians, *THE LANCET*, 1916, i., 887.

<sup>2</sup> Glynn, A. L. Robinson, &c., 1917.

died down through 1903 and 1904, and has been almost quiescent until now. Previously to that there was a moderate outburst of it in 1893, about 2400 cases in London. Previously to that again, it was severe in 1885 and 1884, in each of which years there were about 6000 cases. In 1881 there were 6000 cases in London; prior to 1885 in London it was constantly prevalent, often in the thousands per annum for years together. In 1871, a very heavy year, there were 13,000 cases in London.

There has never been recorded before a period of small-pox quiescence so long as from 1903 to 1919, i.e. 16 years. The previous longest quiet interval was about 8 years. Prophecy of when small-pox will be epidemic again is futile; the practical thing is to be prepared for whatever may come. All that can be said is that it is more prevalent than usual this year.

#### *Importations from Abroad.*

At present, as often as it occurs in our country, so often it is extinguished; infection appears neither to remain nor seriously to spread. But it is being continually reintroduced from abroad, from ports such as Oporto, Lisbon, Bombay, Salonica, Alexandria, Naples. Many of the recent importations have been from European and nearer Eastern ports. Soldiers and sailors have been importers of infection. Many of these have been stopped at the ports. Others, however, and the most dangerous, are those who come through in the incubation stage, and are settled at home by the time the disease declares itself.

#### *A Pertinent Question.*

In keeping on the lookout for small-pox by far the most useful practice is to carry continually the question in one's mind, "Can this case be small-pox?" This is a question which can be usefully applied as a touchstone to every case in practice the diagnosis of which is not clear. Overlooking small-pox is mainly due to the possibilities of small-pox never having crossed the mind. It is a disease of extraordinarily deceptive qualities. Take its stages from the beginning. Onset simulating rheumatism, lumbago, influenza, to mention only a few. Prodromal rash simulating measles, scarlet fever, urticaria, for instance. Hæmorrhagic small-pox simulating meningitis, ulcerative endocarditis, septicæmia, among others. Severe confluent small-pox resembling measles, perhaps, or showing little sign of illness at all, because there are no spots, but only one spot; the skin of the face slowly rising (till early death) in one vesicle. Then there is the rash proper of a moderate case with a host of disguises: chicken-pox, syphilis, dermatitis, pustular eczema, scabies, impetigo, acne, and many more. These are not fancied, but are very close resemblances, as the rash passes through its various stages of papule, vesicle, pustule, ulcer, scab. Then there is the last stage of all, when scabs under the hard skin of the feet and the reddish scars elsewhere may be the only, but yet unmistakable, mark of small-pox.

#### *Value of a Second Opinion.*

Directly suspicion is aroused it is well at once to certify and get removal, or to get a second opinion. I recall very well a case where an action was brought for damages caused by an error in diagnosis. As soon as the jury were shown that the medical attendant had used all his skill and care and had also called a second opinion, they stopped the case and found for the defendant. Had this not been done, he would probably have had to pay heavy damages.

#### *Diagnosis.*

As to clinical details of diagnosis, reference is suggested to the various sources mentioned below. As I was a pupil of the late Dr. T. F. Ricketts and have worked by his methods for 22 years I naturally prefer them. They are set out in his "Diagnosis," with Dr. J. B. Byles's superb photographs; in my "Diagnosis," "Illustrative Cases," and "Differential Diagnosis between Small-pox and Chicken-pox."

For one faced with a suspected case it is best to take first the pathological features, especially the rash of the case, the history last, and to weigh all the evidence as a whole. The surest single guide is the distribution or arrangement of the rash on the skin. The key to that is that the rash of small-pox especially favours skin which is vascularised by irritation or exposure. May I also add this? Withhold an opinion in a doubtful light. Get the very best light possible. See the whole of the skin and as much as possible in one view. The sitting-up posture in

bed, the patient stripped to the waist and his arms crossed in front, is very useful.

The quickest and soundest method of learning the rudiments of diagnosis, apart from seeing actual cases, is to spend an hour with a stereoscope and some good stereoscopic photographs, with a small-pox date card and some explanation.

#### *Facts for Antivaccinators.*

With antivaccinators I have usually found most good can be done by setting out the facts when temperately asked for and by avoiding argument. I say that I am as much entitled to my opinion as they to theirs. When small-pox threatens it is worth while asking the question, What are you going to do about it? Are you going to gamble on the risk of taking small-pox, or make a certainty, at considerable present inconvenience, of safety? I found this kind of reasoning effective during the war with convinced antivaccinators, and learnt from many of them with whom I served that much opposition to vaccination comes from the facts never having been put to them. Further information on this point is in my "Lecture to Soldiers on Small-pox and Vaccination."

It is worth noting that successful vaccination within the first 48 hours of the incubation period of small-pox prevents an attack; vaccination can be performed later, but then it has little or no protective effect.

## VACCINATION BY SUBCUTANEOUS INJECTION.

By J. R. GOODALL, O.B.E., B.A., M.D., C.M., D.Sc.  
(McGILL UNIV.), F.A.S.G.,

MAJOR, C.A.M.C.; ASSISTANT PROFESSOR OF GYNECOLOGY, MCGILL UNIVERSITY, MONTREAL.

In the spring of 1915, while attached to the Canadian Mounted Rifles as medical officer, I came frequently in contact with Dr. George Hume, of Sherbrooke. We discussed the question of vaccination of troops by subcutaneous injection. He had done a few cases in this way, and before inflicting this method upon the men of my unit I had myself vaccinated by Dr. Hume. I had been vaccinated ten times previously without success. Within three days my arm was sore, and I went through all the general symptoms of successful vaccination.

Since then I have vaccinated hypodermically approximately 6000 men and quite a number of officers' children.

#### *Method of Preparing Vaccine.*

It was impossible to procure vaccine in bulk, so vaccine put up in the small capillary glass tubes was used in the majority of cases.

These vaccine tubes were first placed in methylated spirit for a few minutes, then withdrawn singly by surgically clean or gloved hands, the excess alcohol wiped off with sterile absorbent cotton, the ends broken off, and, lastly, the sterile rubber bulb fixed to one end of tube to blow out the vaccine into a sterile beaker. The vaccine generally shoots out of the tube into the beaker in the form of a small cylinder.

When the vaccine available was in small wax tubes the extreme end was first punctured with a sterile needle and the vaccine squeezed out by compressing the container. From

one-half to three-quarters of a tube of vaccine was used per individual. Sufficient sterile water was then added to the vaccine to make each injection equal to 1 c.cm.

In private practice, or where one or two only are to be vaccinated, the vaccine may be prepared as an ordinary hypodermic injection, using vaccine instead of a drug.

Patients can be vaccinated with great rapidity. After preparation of the vaccine four medical officers vaccinated 1100 in two and a half hours by using 20-c.cm. Record syringes and injecting 1 c.cm. into 20 consecutive men, changing the needle after each injection.

#### *Technique of Injection.*

The arm was sterilised with iodine and the vaccine injected diagonally with a fine hypodermic needle and syringe into the subcutaneous tissues. In a few cases by mistake the vaccine was injected intracutaneously.

Everything should be done with surgical cleanliness.

#### *After-effects.*

The local reaction sets in usually between two and four days, but in a few cases the reaction is considerably delayed, and in one colonel's family three children were vaccinated, and reaction did not appear until 12, 13, and 15 days respectively. The local reaction is much like that following antityphoid inoculation and just as variable in intensity. About 8 per cent. proved ineffective, showing but slight local reaction, not more than perhaps could have been accounted for by the iodine applied to the skin; in 70 per cent. (approximate only) there was a reaction similar to the usual reaction after antityphoid inoculation—i.e., local swelling, heat, tenderness, slight pain, and redness. In a small percentage of cases the reaction was marked, causing swelling and œdema of the elbow, and in a few œdema involving the whole arm and hand.

In every one of the 6000 cases vaccinated hypodermically by myself or under my supervision (for all of whom I myself prepared the vaccine for injection) the local condition subsided without any signs other than those of excessive local reaction.

After the seventh or tenth day the local swelling and induration subside, leaving a hard nodule in the subcutaneous tissues, usually ill-defined at first, becoming later well circumscribed and lasting for about one month. This is quite painless after the first acute reaction. The process differs in no respect from that of an antityphoid reaction, except that the onset is slower and the reaction spreads itself over several days.

The general symptoms vary in intensity and do not differ from those of ordinary vaccination.

#### *Infection.*

In the 6000 cases quoted there was not one case of infection. This can be stated without question of doubt. The men were all soldiers who came directly under me and my medical officers for observation and for sick parade. They were all seen several times afterwards, and in about 50 per cent. of cases the vaccination was done at the same time or between the regular antityphoid inoculations. I saw one case of infection in another brigade; this was brought to my attention, and on close questioning it was found that there had been faulty technique. There was a punched-out ulcer, about the size of a halfpenny, exposing the fascia. The ulcer healed without untoward result.

None of the 6000 required dressings, and the men were not exempted from anything but physical training and rifle drill. A percentage were given light duty, and a very small percentage were excused duty for a few days, owing to excessive local or general reaction. There were no hospital admissions. In a few cases (about 10 altogether) the vaccine was injected intradermally, and about four or five days later there developed the typical vesicular and pustular stages of ordinary vaccination, quite uncomplicated.

#### *Advantages of the Method.*

1. This is a clean surgical operation. If untoward results develop they are due to faulty technique.
2. There is no open wound, and therefore dressings are not required.
3. Dangers of secondary infection are practically eliminated.
4. The percentage of positive reactions is very high.
5. In only a small percentage of cases the local and general symptoms caused complete incapacity.
6. It is painless as compared with scarification.
7. Children undergo the hypodermic vaccination without any difficulty, owing to the rapidity with which the injection is carried out.

## Reviews and Notices of Books.

*William Howard Lister.* By WALTER SETON. With a Foreword by Lieutenant-General Sir IVOR MAXSE, K.C.B., C.V.O., D.S.O. Printed for private circulation by Philip Lee Warner, Publisher to the Medici Society, Ltd., Grafton-street, London, W. 1919.

THE Life of William Howard Lister, Captain, R.A.M.C., by Walter W. Seton, LL.D., will interest a wider circle than that of the University College men for whom it is primarily intended. Senators of the University of London might read it with advantage, and the general public will find the incidents of this short life to be of thrilling interest. Though of Quaker stock, and educated at a Quaker school, he was eminently a fighter; not, however, for fighting's sake, but as a champion of good causes. Three or four such contests are a good record for one who had only reached the age of 31. He entered heart and soul, from the student's point of view, into the vain struggle to make the University into a real University of London; and in an unobtrusive way he was the instigator and leader of some of the more active movements of the London students of his day. Amongst these was the incident of the "Brown Dog" at Battersea, which is graphically described. The reader will see that it was not, as some thought, a mere piece of rowdiness, but a fight for a principle which was backed up by newspaper articles and debating society discussion. It was an easier task to cultivate the spirit of comradeship amongst his fellow students than to start such a spirit amongst the students of the University. His untiring efforts in this direction had much to do with the successful origin of University College Hall.

But the real spirit which inspired him is most clearly, though all too briefly, shown in the account of his service during the war. He was one of the first dozen qualified men to obtain a commission in the R.A.M.C. and was in time to take part in the battles of the Marne and of the Aisne, and, except for sick leave, he was continuously with the Army till he was killed on the Italian front in August, 1918. He was not one of those who do not know what bodily fear is, and the excitement of battle had no attraction for him. He was always anxious lest his courage should fail, but when the time came nothing could keep him from the place of danger. In a letter to a personal friend, dated B.E.F., France, March, 1918, he said:

"We are all of us a little grave and anxious out here, waiting in this quiet before the storm, not about the ultimate result, of course, for of that there can be no doubt. But there's going to be deadly work this year, and with so many splendid fellows round one, one wonders more than ever at the wickedness and beastliness of it all. The people I am with now are the most charming I have yet met, and I only pray I may be able to do my full duty by them."

His power of organising was great, and everywhere he inspired enthusiasm. Sir Ivor Maxse, in a foreword, says:—

"In fact, his eager temperament and immovable standard of duty made him indispensable to the troops whenever fighting was on, and we all recognised his value from the last recruit to the divisional commander."

Dr. Seton tells the story very simply, clearly, brightly, and without redundancy. There is not a dull page in the book. He is fortunate in having almost equally acceptable writers in the two friends who have supplied the longest quotations. It is a good testimonial for the author that one closes the book with regret and wishes that it had been longer. It is beautifully produced, and those who desire copies can obtain them from the senior clerk, University College, London, Gower-street, W.C.

*Practical Vaccine Treatment for the General Practitioner.* By R. W. ALLEN, M.A., M.D., B.S., late Captain, N.Z.M.C. London: H. K. Lewis and Co. 1919. Pp. 308 + ix. 7s. 6d. net.

THIS little volume contains a fund of useful information on the subject with which it deals. After an autobiographical introduction, in which the author claims that never in the past 12 years has he misled his readers on the subject of vaccine treatment, he passes on to explain the rationale of vaccine therapy in its varied forms. He is impatient of those who cannot distinguish between vaccine

and serum. He holds—and we think rightly—that every case undergoing vaccine treatment is “a law unto itself,” and therefore it is illogical to lay down beforehand any hard-and-fast scheme of dosage. The inference is that the clinical pathologist should give his own vaccines; but whereas it may conceivably be true, as Dr. Allen contends, that no dermatologist is a sound bacteriologist, it does not necessarily follow that every clinical pathologist is a sound physician.

The author's ruling principle in the administration of vaccine is to give the smallest dose which suits the patient, and he gives some sound advice on technique—e.g., “Use good tools and get it over and done with as quickly as possible.” To this axiom we should add the rider: “See that in your haste you have not injected vaccine into a vein unless you wish to do so.” He deprecates the employment of detoxicated vaccines as being unsound in principle. He is aware of the bearing on success of the barriers to the action of vaccine occasioned by want of access, as from fibrin in pneumonia and scar-tissue in wounds, and he illuminates this pitfall for the unwary. A novel and useful feature for the inquiring mind is the appendix of questions and answers as regards vaccines.

We find the author's experience entertaining, but we should like to know more of his failures in order that others may learn to share his successes. He is not always consistent. On one page we read that the staphylococcus forms endotoxin and endotoxin alone, and on the same page, a few lines further down, we are told that the staphylococcus forms one endotoxin and two exotoxins. Whereas it is twice stated that the author has never lost a case of septicæmia, we read that in relation to infective endocarditis of a streptococcal nature (and is not this septicæmia?) a few *successes* (the italics are ours) are on record!

The author has many lances to tilt, mostly “agin the Government,” and has apparently been “laughed to scorn” quite a number of times. Referring to pensioners or other discharged soldiers who may be dysentery carriers he writes: “..... what steps the Army or Government will take once they have been discharged, Heaven only knows,” a surmise which may be true, but does not presage well for a judicial survey of a difficult subject.

If he does not surrender his own judgment, the practitioner will find Dr. Allen's book useful to him.

*The Newer Knowledge of Nutrition: the Use of Food for the Preservation of Vitality and Health.* By E. V. McCOLLUM, School of Hygiene and Public Health, the Johns Hopkins University. Illustrated. New York: The Macmillan Company. 1919. Pp. 200. 6s. 6d.

REGARDLESS of the outcome of future studies relating to the importance of diet in the etiology of such diseases as pellagra, tuberculosis, and allied disorders, the author essays to give a non-technical presentation of the kinds of combinations of our natural foods which induce good or faulty nutrition in animals. This should be of service in showing the inadequacy of the practice, which is still in vogue, of regarding calories as the only factor of importance in the planning of the diet. It is neither necessary nor desirable to abandon the customary classification of food-stuffs. The author's great point is that a chemical analysis of a foodstuff may throw no light whatever upon certain aspects of its dietary properties, and that only by biological methods can we arrive at principles which can serve as a safe guide to the planning of a safe dietary.

The biological method for the analysis of a foodstuff is first dealt with. Over 3000 feeding experiments, most on domestic rats, and some on farm pigs, cattle, chickens, and guinea-pigs, were made, and in the result it is found that “the chemical requirements of these different types of animals are essentially the same.” It was only in 1897 that the first fertile suggestion was made by Eijkmann as to the dietary fault causing beri-beri. The various feeding experiments by other observers with purified proteins, amino acids, &c., are explained, as well as how it comes about that under certain conditions neither maintenance of body weight nor growth could be secured with such diets, and why the addition of certain unidentified food substances restored the balance. The relation of a diet of polished rice to experimental beri-beri and the “vitamine” hypothesis of Funk led up to the discovery of two classes of unidentified

substances as necessary constituents of a normal diet to which the terms fat-soluble A and water-soluble B were given. We need hardly refer readers of THE LANCET to the large literature on these points. A most interesting chapter is devoted to experimental scurvy and the dietary properties of vegetables. Guinea-pigs restricted to a diet of oats develop scurvy in a few weeks. All the “seeds”—wheat, oats, rye, barley, &c.—examined resemble each other very closely in their dietary properties, and all have important dietary faults, so that it is not possible to secure appreciable growth in young animals fed exclusively upon seed products as the sole source of nutriment. There seems to be no species of the omnivora which subsists entirely upon seeds. Appropriate mixtures of leaf and seed make fairly satisfactory food mixtures, and the author gives his reasons why the leaf should show such decided dietary differences as contrasted with the seed. The tubers and roots employed and their characteristics, more especially as regards the solubles A and B, are passed in review. The short chapter on the Vegetarian Diet is most suggestive, and so is the next on Foods of Animal Origin. Milk is our most important foodstuff, for in addition to the extraordinary value of its protein, when used in combination with the foodstuffs of either animal or vegetable origin, it corrects their dietary deficiencies. Milk and leafy vegetables and eggs are regarded as *protective* foods. The author is loud in his praises of milk; indeed, according to him mankind can be classified into two groups. Both groups have derived the greater part of their food-supply from seeds, tubers, roots, and meats, but differ in the character of the remainder of their diet. Those peoples—Europeans and North Americans—who have made liberal use of milk as a food, in contrast with those peoples—Chinese, Japanese, and people of the tropics generally—who have made use of the leaf as their sole protective food, in the words of the author—

“have attained greater size, greater longevity, and have been much more successful in rearing their young. They have been more aggressive than the non-milk using peoples, and have achieved greater advancement in literature, science, and art. They have developed in a higher degree educational and political systems which offer the greatest opportunity for the individual to develop his powers. Such development has a physiological basis, and there seems every reason to believe that it is fundamentally related to nutrition.”

In the United States 15–25 per cent. of the total food-supply is from the products of the dairy. Milk is the greatest factor of safety of our nutrition. Its value cannot be estimated on the basis of its content of protein and energy. It has a value as a protective food, improving the quality of the diet, which can be estimated only in terms of health and efficiency. The last chapter deals with the nursing mother as a factor of safety in the nutrition of the suckling.

This is a record of laborious and painstaking work on an important and urgent subject, illuminated by penetrating criticism and suggestive practical applications. It largely modernises and fructifies our ideas of the importance of food and feeding, while demonstrating how little we know as yet of the intimate factors of nutrition. Altogether a wonderfully suggestive contribution to the elucidation of some of the obscure phenomena of the physiology of metabolism in its widest sense.

*Health Resorts of the British Isles.* Edited by NEVILLE WOOD, M.D. Second edition. London: University of London Press, Ltd. 1919. Pp. 254. 6s.

THE present is an auspicious time for the publication of a second edition of this book. For one reason or another many patients will be prevented for many years to come from visiting the famous centres of hydrology on the continent. At the same time, owing to the efforts of a few English physicians, the importance of hydrology is at length being realised in this country, and there are prospects of a scientific development of our own not inconsiderable resources. As Dr. Wood points out, there are important mineral springs scattered throughout the Empire, and it is unfortunate that the medical men coming from our own overseas dominions should have to seek on the continent that post-graduate instruction in hydrology which we are at present unable to provide.

The lesser as well as the better known British watering-places are all noticed in this book, and their virtues, whether for baths, climate, or sunshine, are duly recorded.

There are numerous illustrations, many of which are already well known to those who travel. More important, perhaps, are the analytical tables which are given from time to time, and of which there might be even more with advantage to the medical reader. Some districts are necessarily better reported than others. The accounts furnished by medical committees and societies are obviously the best, and an increasing interest on the part of medical men in their own districts will doubtless lead to a continued improvement of this useful volume.

## JOURNALS.

IN the *Military Surgeon* for June Colonel H. L. Gilchrist describes the "mobile degassing station" devised by himself as Medical Director of the Chemical Warfare Service of the American Expeditionary Force. They were required to deal with damage to the mucous membranes by acid and chlorine and with damage to the skin by mustard gas. They had a blue flag by day, a blue lantern by night. When the men arrived any who showed gas symptoms were at once treated and sent on to hospital, the others were divided into groups of 24 for bathing and re-clothing. These last, after laying down arms and loose equipment, neutralised their hands and shoes with dry lime, and their helmets with lime water, the helmets being hung on numbered shelves. The men then undressed, stepped under the showers, sprayed themselves with liquid soap, the hot showers were turned on for 15 seconds, 45 seconds were allowed for washing, and the showers were then turned on again for 30 seconds to remove the soap. Each man had a clean towel. Eyes, noses, and throats were then sprayed with 5 per cent. solution of sodium bicarbonate, the men were inspected naked by medical officers, were served out with fresh uniform and underclothes, and returned to their units. The degassing unit was essentially a motor truck carrying a 1200-gallon tank, a rotary pump, and a device for heating the water; a portable

shower apparatus with 24 shower-heads like a pergola made of 2-inch tubing with sliding joints and standing 7 ft. 6 in. above ground; a hospital ward tent used as a bathing and dressing tent; and wagons to carry the stores and clothing. The baths could thus be taken to the troops, the showers could be erected in two minutes, the whole outfit in 17 minutes, and packed up again in nine. 160 outfits were ordered by the Army.

In the same issue Brigadier-General F. Winter, Medical Corps, U.S. Army, recounts the trials and triumphs of the Medical Corps, starting from crowded St. Nazaire, where surgical specialists helped the needed hospital outfit from the ships to the cars, through the difficulties of sanitation in France when deficiency of tonnage kept appliances short, and the early discomfort of hospitals when cargoes of linoleum were sunk by submarines, and Carrel-Dakin solution froze in the wards, and lice had not yet been mastered. It was enthusiasm for General Pershing and his leadership, General Winter thinks, that inspired all ranks to make the war machine work to best advantage; everyone helped, doctors, nurses, and orderlies. He claims great results for preventive medicine: 45,000 deaths from wounds, 22,000 from disease, including pneumonia, which, by the way, attacked least of all the 1st Army Corps in bivouac. He believes it was loyalty to their families that kept the U.S. soldiers off alcohol, and here they were greatly assisted by the Y.M.C.A. He pays a generous tribute to the work of the Red Cross, which was not only always friendly and open-handed with stores, but, looking ahead, published for the young army a book of the splints they might best use, and set up a factory in France to make them. He proudly quotes from Sir Arthur Stanley that the people of the United States raised more than five times as much for the Red Cross as was raised in England, but we must remember that the United States have had nothing like our war taxation. All American officers, speaking in the United States, give most cordial thanks to the French and ourselves for our sympathetic co-operation.

\* No returns.

† Excessive rainfall, bottle overflowed.

Tr. = trace.

"Tar" includes all matter insoluble in water but soluble in CS<sub>2</sub>. "Carbonaceous" includes all combustible matter insoluble in water and in CS<sub>2</sub>. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 9 lb. per acre; (b) 2.56 English tons per sq. mile; (c) 1 g. per sq. metre; (d) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

# THE LANCET.

LONDON: SATURDAY, AUGUST 16, 1919.

## The Reorganisation of Pensions.

THE speech of Sir LAMING WORTHINGTON EVANS, the Minister of Pensions, in asking the House of Commons, sitting as Committee of Supply,<sup>1</sup> to agree to the supplementary vote of £45,855,000 for the Ministry of Pensions, has helped the nation to realise the responsibility imposed by the care of its injured sailors and soldiers. A nation yet unborn will gather the aftermath of the world-war and see the last maimed pensioner carried to the grave from which the surgery of this generation saved him. It is with the sailor or soldier disabled by his service that our profession is chiefly concerned; it is here our assistance is indispensable to the carrying out of the work of the Ministry. The granting of pensions to the widows and dependents of the dead is another branch of pensions work, for which medical advice is essential, being invoked chiefly when there is doubt whether death by disease should be attributed to war service. The figures relating to pensions are instructive, and may do something towards explaining the occurrence of delays and mistakes in a department newly organised in the midst of war, of whose duties the granting of pensions to the injured and to dependents forms only one part. Pensions, gratuities, and final allowances during the past 12 months have been considered in respect of more than two and a quarter million persons, including officers, nurses, and men, with their widows, their children, and their other dependents. The annual payment at present comes to near £100,000,000, though this sum is subject to reduction in the future, not only by the deaths of pensioners, but by the cessation of gratuities that will not have to be repeated. Moreover, no pensioner, wounded or invalided at any date in the war, will leave the protection of the Pensions Ministry save under proper medical certification that he is fit to undertake the training proposed for him by the Ministry of Labour.

The part to be played by medical men in future pension administration was considerably insisted upon by the Minister of Pensions, who described the procedure in detail. The medical boards for men applying for pensions, or for the renewal of them, passed on April 1st out of the hands of the Ministry of National Service into those of the Ministry of Pensions, which department took over on August 4th from the War Office responsibility for the Re-survey Boarding of Officers. This is a task which demobilisation has rendered very heavy, and during the six months ending with last June medical boards were held upon 229,697 men. At the same time, and owing to the process of demobilisation, there has come under the jurisdiction of the Ministry the care of the disabled, including their treatment in hospitals, clinics, and convalescent centres. Colonel WEBB will be the chief medical officer, under whom a medical, surgical, and nursing staff will carry out the duties assigned to them by the Ministry, among which will be the provision of artificial limbs and their repair. These increases in the sphere of the

activities of the Ministry of Pensions will, however, be of less interest to the public than the steps which are promised for reorganisation of the work of the department. There has been public expression of dissatisfaction, which may have been exaggerated but has not been altogether baseless, and the existence of which cannot be denied. A system by which medical officers at the headquarters of the Ministry were empowered to review the decision of a medical board, and by which a medical officer was authorised to alter the amount of a man's assessment, though made by a board, without himself re-examining the case, was one which, in popular phraseology, "asked for trouble." There are now to be Medical Appeal Boards to which the medical assessor of the Ministry may refer a case, if not satisfied, on the perusal of the papers in it, that substantial justice has been done to the pensioner or to the taxpayer. For the taxpayer must be protected. To these boards the pensioner himself will have a right to appeal, if not satisfied with the amount awarded him, and such re-examination should do much to justify the finality assigned to the decision which will then follow. In a question of incapacity the body of the man concerned supplies an essential part of the material required for the consideration of his case, and a summary or statement of the observations and conclusions of others, whether medical men or not, cannot satisfactorily be substituted for it.

In addition to the Medical Appeal Boards there will be, we understand, other new tribunals set up as the result of the report of the Select Committee recently published, and these will be independent of the Ministry of Pensions, and appointed by the Lord Chancellor when a Bill for that purpose has been duly passed. Their functions will be to consider appeals by a claimant of a pension in cases of its refusal either on the ground that the disability was not attributable to, or not aggravated by, military service, or on the ground that the disability was due to serious negligence or misconduct of the claimant. They will also review refusals of pension to a widow or dependents on the ground that the sailor or soldier's death has not been due to military service. These tribunals will be composed of a barrister or solicitor as chairman, a medical practitioner, and a disabled officer or disabled man, according to whether the case to be considered is that of an officer or of one not holding a commission. Thus a statutory right will be granted, as distinct from one arising out of a Royal Warrant, to claim a pension before an independent statutory court, whose decision will be final. This court will have to decide, we may add, one of the most difficult of the many complex questions that arise in the granting of war pensions. A man may have entered the Army an apparently healthy man, or with an admitted unsoundness. He may have faced the rigours of one or more winters in the trenches and returned to develop disease, ending in death or disability, in the healthy surroundings of his home or of a well-ordered camp in the United Kingdom. Naturally, to him or to his surviving relatives it is clear beyond demonstration that his war service is the responsible cause of a result which otherwise would never have supervened, and yet it may not be so. We urge in such a case a liberal consideration of the facts, medical and otherwise, with the benefit for the claimant of such doubt as science may not be able to clear up. We are not, however, altogether in accord with the observations

<sup>1</sup> THE LANCET, August 9th, p. 267.

of Dr. D. MURRAY in the House of Commons when he said that this question of the attribution of disease to war service should not be put to a medical board at all. We agree with him that it is a cruel duty, and one the perfect fulfilment of which is wellnigh impossible. We regard the matter, however, as one essentially for medical decision, and we are inclined to ask ourselves whether an appeal tribunal with a majority of laymen upon it can really do more than relieve a medical board of a painful responsibility. Whether it supports or overrules a medical board's decision, it can hardly add weight to it. It is our fervent hope that the changes introduced by the present Minister of Pensions may result in his department combining justice with generosity, and giving that degree of public satisfaction which is essential to the smooth working of the affairs of the State. It has to create its own standards and to live up to them. The standards of pension administration created by previous wars are not merely obsolete; they were never altogether worthy of the occasions which called them into being.

### Ernst Haeckel.

THE death is announced at the age of 85 of Professor ERNST HAECKEL, who attained world-wide reputation as a biologist, a zoologist, and an apostle of Darwinism in Germany; later he secured notoriety as an expounder of a theory of the universe by which he settled, according to his own satisfaction, such problems as the existence of GOD, the freedom of the will, and the immortality of the soul. In addition to these labours he travelled widely in the East, and during the war was an embittered opponent of Great Britain and an ardent upholder of the German cause. He was a skilled artist both with the brush and the lead, and his books of travel were illustrated with his own hand, while many of his biological and zoological works were also embellished by him with magnificent drawings, both coloured and uncoloured. HAECKEL's chief claim to fame is that when quite a young man at the very beginning of his scientific career, apart from medicine, he read and at once accepted DARWIN's thesis as laid down in "The Origin of Species." He was the first German biologist to do so, and he maintained his position in opposition to many of the foremost thinkers in Germany, among whom the most prominent was VIRCHOW. Before very long, as every one knows, DARWIN's doctrine of evolution was accepted in scientific circles in Germany as well as elsewhere. HAECKEL's mind, however, worked on different lines from that of DARWIN, who was eminently cautious and who worked by amassing particulars and from them formulating a general rule. HAECKEL considered that the doctrine of evolution could be applied to the solution of all problems wherein men or animals are concerned with almost the certainty of mathematical laws, and in upholding this thesis he was as bitter and dogmatic as any of the clericals against whom he so often tilted. Thus, we find him saying in "The Riddle of the Universe" (we quote from the shilling edition of 1913), on p. 12:—

"In the famous speech which Emil du Bois-Reymond delivered in 1880 in the Leibnitz session of the Berlin Academy of Sciences he distinguished seven world enigmas, which he enumerated as follows: (1) The nature of matter and force; (2) the origin of motion; (3) the origin of life; (4) the (apparently pre-ordained) orderly arrangement of

nature; (5) the origin of simple sensation and consciousness; (6) rational thought and the origin of the cognate faculty, speech; (7) the question of the freedom of the will."

HAECKEL goes on to say that DU BOIS-REYMOND considered three of these problems entirely transcendental and insoluble—namely, problems 1, 2, and 5; three others, problems 3, 4, 6, capable of solution though difficult; while as to problem 7 he remained undecided. HAECKEL sweeps all doubts away as follows:—

"In my opinion the three transcendental problems (1, 2, and 5) are settled by our conception of substance; the three which he considers difficult though soluble (3, 4, and 6) are decisively answered by our modern theory of evolution; the seventh and last, the freedom of the will, is not an object for critical, scientific inquiry at all, for it is a pure dogma, based on an illusion, and has no real existence."

HAECKEL's "law of substance" is the combination of the fundamental chemical law of the constancy of matter with the fundamental physical law of the conservation of energy, and according to him it definitely rules out the three central dogmas of metaphysics—GOD, freedom, and immortality. We can expand this doctrine in the words of Mr. JOSEPH McCABE, who is HAECKEL's warmest supporter in this country, by the following quotation from his "Haeckel's Critics Answered," where he says that HAECKEL concludes—

"That the thinking and willing force in man—what we call his mind or spirit—is identical with the force that reveals itself in light and heat. In other words, he is forced to think that spirit and energy are one and the same thing, and so he uses the names indiscriminately. But he is further convinced ..... that matter and spirit (or force) are not two distinct entities or natures, but two forms or two aspects of one single reality, which he calls the fundamental substance. This one entity with the two attributes—this matter-force substance—is the sole reality that exists."

Belief in GOD is not the exploded idea that HAECKEL seemed to consider it, nor can we see how belief in the two cardinal doctrines of the conservation of matter and energy necessarily rules out belief in GOD. But here HAECKEL showed the typical psychology of the Prussian. Just as the pan-German—i.e., Prussian—ideal was that the whole world should be ruled and governed by Prussian kultur, that phase of psychology being the one and only mental attitude which possessed any real good, so HAECKEL held that belief in the law of substance explained all the problems which have exercised the mind of man for centuries, whence it followed for him that anyone who did not hold with his ideas was a gross obscurantist.

We turn with relief from HAECKEL the Monist philosopher to HAECKEL the biologist. In that field he undoubtedly did excellent work; his championship of DARWIN at a time when that great observer's views were generally looked upon with disfavour is greatly to his credit, and the biological museum which he gradually formed at Jena is comparable to the immortal HUNTER's museum in London. His "General Morphology" was highly praised by HUXLEY, while DARWIN gave similar praise to his "History of Creation." As to his views on the war, which, when they were published in October, 1914, rightly aroused indignation, we can, now that their author is dead, feel nothing but pity that one of such intellectual gifts should have associated himself with 92 other professors in glorifying the atrocities in Belgium and the German doctrine of kultur and militarism. His work as a biologist will stand as a whole, although it was undoubtedly defective in part; his philosophical and political views will be buried in oblivion.

## Annotations.

"Ne quid nimis."

### THE BIRTHDAY HONOURS.

ON the occasion of the celebration of His Majesty's birthday the King has conferred honours upon three members of the medical profession—namely, Lieutenant-Colonel Harry Gilbert Barling, Dr. Robert Charles Brown, and Mr. William Ireland de Courcy Wheeler. Lieutenant-Colonel Harry Gilbert Barling, who becomes a baronet, is the Vice-Chancellor of Birmingham University, where he has been Ingleby lecturer and dean of the medical faculty; he has also been examiner in surgery at the University of Cambridge. His public services during the war were of the first importance. Dr. Robert Charles Brown, who becomes a knight, is consulting medical officer of Preston Royal Infirmary and the founder of a scholarship for research at Cambridge. His work in connexion with the promotion of infant welfare has been indefatigable. Sir W. I. de Courcy Wheeler has rendered valuable scientific and organising service during the war, and is a member of the Consultative Committee of the War Office. Sir J. Y. W. MacAlister, secretary of the Royal Society of Medicine and its parent society for 32 years, is President of the Library Association, started and acted as secretary of the War Office Surgical Advisory Committee, and organised the Royal Army Medical Corps Bureau and an Emergency Surgical Aid Corps for the Admiralty, the War Office, and Metropolitan Police during the air raids. To these gentlemen, in the name of the medical profession, we heartily tender congratulations for well-deserved honours, and while doing so include the name of Mr. Laurence Richard Philipps, the founder of the Paraplegic Hospital in Wales, who becomes a baronet, and of Sir Henry Francis New, the mayor of Marylebone, and vice-president of Marylebone War Supply Hospital, whose knighthood has been thoroughly earned.

### EXPERIMENTS ON OUTPUT.<sup>1</sup>

THE first two publications of the Industrial Fatigue Research Board are a good augury of the high standard of future issues to be expected from this recently established board. They deal with subjects of paramount importance in the present industrial unrest. Miss Ethel E. Osborne's report is based on the hourly output of 43 women in a National Ordnance factory, who were employed on a particularly heavy and rapid operation in the turning of six-inch shells. Data from two shops were obtained of the hourly output for all operators for a whole week during two shifts, day and night, of 12 hours each, before hours were readjusted so as to replace those two shifts by three shifts of eight hours each; whereupon, after the lapse of five months so as to allow of adaptation to the new conditions, a fresh series of data was collected under precisely comparable conditions, the only variable factor being the alteration in the hours of work. The resulting relatively small increase in hourly output under

the short shift system depended on the large proportion of the working time which was absorbed by automatic machinery operations, the speed of which was constant and beyond the workers' control. But in the work of fixing and removing the shells, over the speed of which alone the operator has control, the time required for a fixed amount of work shows a decrease of 19·5 per cent. in favour of the shorter shift. (In the shorter shifts the average worker's hours in the factory seem to have been about 15 per cent. less than in the longer shifts.) Miss Osborne also shows that there was a drop in possible output of 3·43 per cent. for the long shift as compared with a drop of only 0·58 per cent. for the short shift—i.e., the machinery became more efficient and there was less idle time in the short shift. Moreover, during the last hour of each shift the 12-hour shift showed a constant, well-marked diminution in output, whereas no such uniformity exists in the case of the short shifts; on the contrary, several sets of curves exhibit no falling off. The curves of output for the short shifts give evidence of the possibility of running at full output right to the end of the shift; but the curves for the long shifts give no such evidence.

Dr. Charles S. Myers's report describes the remarkable effects of movement study, reduced hours of work, and an improved system of payment on output at the Derwent Foundry Company, Ltd., Derby. The workers were voluntarily trained in the best methods of casting, moulding, &c. Their hours were reduced from 54 to 48 per week. As soon as a worker reached 60 per cent. of "standard output" he began to receive a bonus on his piece-rate earnings, which was so contrived that the price paid per piece rose automatically with increasing output. Under this scheme the increase in hourly earnings amounted to about 200 per cent. in one instance examined. The output increased by more than 300 per cent. No evidence of increased fatigue was found, save, perhaps, in the case of two workers who had enormously increased their output and were producing far above "standard output." There was no complaint of increased monotony under the new system, and the workers were unanimous in their preference for it. The value of such a report as this needs no emphasis in the present industrial crisis.

### MORAL IMBECILITY.

IN the case of a man named Edward Noel Craven, convicted at the Central Criminal Court of obtaining property by false pretences, it was urged at his trial that he ought to be dealt with as a moral imbecile under the Mental Deficiency Act, 1913. He was, however, convicted, as stated, and sentenced to three years' penal servitude. From this he appealed to the Court of Criminal Appeal. He was a man able to earn a living as an engineer, but had committed many offences of dishonesty, and had been in a home under the Act of 1913. At the trial of Craven a medical witness from that home expressed the opinion that he was a moral imbecile and should be treated as such, but the Lord Chief Justice in giving judgment in the Court of Criminal Appeal held that the judge at the trial did not see his way to make use of the Act, and that he (the Lord Chief Justice) saw no reason for interfering with his discretion. The Home Secretary, he said, might order the examination of the prisoner when he was in prison and his removal to a home. An observation of Mr. Justice

<sup>1</sup> The Output of Women Workers in Relation to Hours of Work in Shell-Making. By Ethel E. Osborne, M.Sc. A Study of Improved Methods in an Iron Foundry. By Charles S. Myers, M.D., Sc.D., F.R.S. Reports No. 2 (price 6d. net) and No. 3 (price 2d. net) of the Industrial Fatigue Research Board, appointed by the Medical Research Committee and the Department of Scientific and Industrial Research. Published by H.M. Stationery Office, 1919.

Shearman at an earlier stage of the appeal may be noted. It was to the effect that the Mental Deficiency Act of 1913 contemplates the existence of homes for persons committed under it, but that there is usually no such home available, and that this had been his lordship's experience when trying such cases on circuit. He added that it was very difficult for a judge at the trial of a charge to investigate satisfactorily the mental condition of the prisoner. The proper deduction would seem to be that the Mental Deficiency Act is, in respect of such matters as those referred to, in danger of becoming a dead letter—first, because sufficient homes for moral imbeciles with criminal tendencies are not provided by the State, upon which the duty of providing them should fall; and, secondly, because the State does not supply for the guidance of judges the medical expert evidence which usually must be beyond the reach of the accused.

#### DEATHS FROM MALARIA IN ENGLAND.

THE Ministry of Health are frequently asked to assist in ascertaining the nature of obscure cases of illness in which a fatal issue has occurred. In two recent instances the post-mortem inquiries made for this purpose by medical officers of the Ministry have shown that the fatal issue was due to malaria. The Ministry are advised that in this country a death from acute malaria would be an exceedingly rare event if all medical practitioners adopted the diagnostic rule that in every case of obscure illness in a demobilised soldier, or other person who has served overseas, a blood film taken early in the illness should be examined. The Ministry have made arrangements by which such blood specimens sent to them for the diagnosis of malaria will be examined and reported on free of charge. The method of taking the specimen is described on p. 11 of the Memorandum, "Suggestions for the Care of Malaria Patients," of which a copy has been supplied to all registered medical practitioners in England and Wales. The specimens should be addressed to the Ministry of Health, Whitehall, S.W.1, accompanied by the patient's name and the name and address of the sender. The cover should be marked "*Malaria Specimen: Urgent.*"

Sir George Newman, Chief Medical Officer to the Ministry, takes this opportunity to add that during the present hot weather there is a possibility that, as regards cases of illness in demobilised soldiers, symptoms which appear to be due to "heatstroke" or other effects of the sun may in reality be due to malaria. Medical practitioners are reminded that in accordance with the provisions of the Public Health (Pneumonia, Malaria, Dysentery, &c.) Regulations, 1919, it is incumbent upon them to notify cases of malaria to the medical officer of health for the district.

#### INFLUENZAL OTITIS.

THE tendency to aural complications in influenza varies considerably in different epidemics. In the winter of 1889-90 and in the following years influenzal otitis was very frequent. In the 1918 epidemic, on the other hand, it was decidedly less common. Farner,<sup>1</sup> assistant at the Zurich clinique for diseases of the ear, nose, and throat, states that from the beginning of July to the end of December 1918, only 85 ear cases visited the clinique, and in another hospital at Zurich only 30 ear cases occurred among 861 influenza patients.

Of the 115 cases, 71 were males and 44 females, 90 were between the ages of 16 and 35, 12 were younger, and 13 older. In 49 the otitis was of the acute catarrhal variety (in 40 unilateral, in 9 bilateral), and in 56 suppurative (in 47 unilateral and in 9 bilateral). The otitis began on the first day of the disease in 23 cases, on the second day in 7, on the third to the seventh day in 45, in the second week in 24, in the third week in 4, and in 12 the date of onset could not be determined. Haemorrhagic vesicles on the tympanic membrane and sanguineo-purulent secretion in the tympanic cavity were seen in 31 cases. In 13 paracentesis was performed. Mastoid irritation was observed in 17 cases and mastoid abscess in 12, in 1 case on both sides. The following organisms were found in the pus: pneumococcus in 5, streptococcus pyogenes in 3, streptococcus mucosus, diplostreptococcus, pneumococcus and diplococcus in 1 each; in 1 the pus was sterile. The course of influenzal otitis, apart from the cases complicated by mastoid abscess, was rapid and favourable, and purely nervous symptoms such as neuralgia and "nervous" deafness were much less frequent and pronounced than was formerly the case.

#### POOR-LAW MEDICAL INSTITUTIONS AND LAY SUPERINTENDENCE.

SEIZING the opportunity afforded by the re-arrangement of certain Government departments, the National Association of Masters and Matrons of Poor-law Institutions is attempting to revive an old controversy by addressing to the Minister of Health and to the public generally a statement in support of the lay administration of hospitals. If this document sets forth the best case which can be made for a departure from established principles, it does not appear that the medical men aimed at have much cause for alarm. The Council of the Association claims for its members "probity of conduct, continuity of work, sympathy, consideration, and a fair holding of the scales between all the interests concerned." It does not state that these qualities are lacking among the medical men who undertake administrative work, though unless that implication is intended to be conveyed the argument has no weight. Accepting, however, the criteria proposed, we think that any unbiassed person would admit that they are most likely to be efficiently presented by professional men with higher education, more profound knowledge of human nature, and wider experience of public affairs than is characteristic of the class, however morally worthy it may be, from which masters and matrons in the Poor-law Service are drawn. Those who have seen the experiment tried know that lay superintendence means divided control and consequent friction—friction which impedes the running of the administrative machine and may bring it to a standstill. There must, in practice, be one head, and as between the qualifications of medical men and workhouse masters to manage institutions for the sick the choice is not difficult. And the question of choice is clearly raised, for in the opinion of the Council "many of our Poor-law institutions are bound to become more and more of the nature of State hospitals." Nor is the matter merely one affecting medical officers. In the Poor-law Service the term "matron" has not the same connotation as in ordinary hospital practice. It is not to be expected that trained nurses will submit to continual interference by a superior officer who is incompetent to judge their work aright and who

<sup>1</sup> Correspondenzblatt f. Schweizer Aerzte, 1919, xlix., 356-9.

has not the technical knowledge which would enable her to be appealed to in case of need. No sane person, so far as we know, has suggested that military hospitals should be placed under the charge of the Army Service Corps, but the plan would have quite as much to recommend it as could be said for the proposals of the National Association of Masters and Matrons of Poor-law Institutions. The practice of appointing medical men as heads of institutions has stood the test of time, and any drawbacks which attach to it are not to be overcome by substituting for a fully qualified officer, one ignorant of the most important part of the duties required.

#### INTERNATIONAL HEALTH AND THE LEAGUE OF RED CROSS SOCIETIES.

WITH the approval of the Ministry of Health, Dr. G. S. Buchanan proceeded at the beginning of the week to Poland to make one of a small International Committee formed at the instance of the new League of Red Cross Societies. This league has been requested by the Polish Government to aid in devising a public health organisation for that sorely tried country in face of the devastating attack of typhus which it has recently experienced, and of other epidemics which are threatened. Dr. Buchanan's collaborators are Professor Castellani (Italy), Professor Dopter (France), and Colonel Hugh Cumming (United States of America), so that each and all of the Committee will be able to advise from close personal experience on the practical ways of preventing and of combating epidemic disease. A great promise may lie behind this announcement, though more than this cannot be said until the League of Red Cross Societies has received the report of the International Committee; for obviously when a country in the special condition of Poland is concerned it may be impossible for the Committee to suggest practical measures; or it may be easy to suggest the measures that should be taken while impossible to give any assurance that public health organisation, however well defined, can live in so distressed an environment. Looking, however, on the brighter possibilities, we see in the appointment of this International Committee, with a mandate to give considered counsel to the League of Red Cross Societies, a prevision of what may be done in the future by the League of Nations, a grand part of whose programme is maintenance of world health by inter-State support. It seems to us that the League of Red Cross Societies may be a very valuable pioneer in those territories of international hygiene which the League of Nations will have to take over.

#### AMPUTATION STUMPS.

MANY accepted principles of surgery remain unchanged by the lessons of the war. For instance, despite all the experience of the last four years, the routine treatment of amputation stumps and the methods of prosthesis remain essentially the same in principle as they were before the war, though they have been much improved in details. No doubt during the times of stress the claims of urgent surgical procedures were so overwhelming that no leisure was left for the trial of methods of which the practical value was not yet established, such as the operations advocated some years ago by Dr. Vanghetti. Now, however, we may hope that surgeons will be able to devise new methods of treatment, and that mechanics may be successful in constructing suitable apparatus

for the improved amputation stump. Two papers which we print in this issue of THE LANCET are doubtless only an earnest of the developments to come. Major Fitzmaurice-Kelly's paper contains nothing, perhaps, startling in its novelty, but it offers what is just now much wanted—namely, a valuable contribution to the technique of the operation for forming plastic motors. In the Pavilion Hospital at Brighton there is a plentiful supply of material, probably unrivalled in the Empire, of which Major Fitzmaurice-Kelly has availed himself, so that he has been able to perform what is perhaps a greater number of kinematic operations than any other British surgeon has yet published. At the present moment most surgeons are sceptical of the practical value of Vanghetti's methods, but the next few months should see the improved plastic motors fitted with suitable artificial limbs and their value established or disproved. The paper by Major W. E. Gallie, of the Canadian Army Medical Corps, records an attempt to lengthen an amputation stump which is too short to be useful, by means of an osteoplastic operation. If sufficient muscular attachments and muscular control can be secured there seems no reason to doubt that this procedure may be of value. As in both Major Fitzmaurice-Kelly's and in Major Gallie's operations the risk of leaving the patient worse off than before is negligible, there seems no reason why these operations should not be repeated until an agreed technique is arrived at.

#### MARINE HYGIENE.

AT the Congress of the Royal Sanitary Institute, held at Newcastle-upon-Tyne from July 28th to August 2nd, Surgeon Rear-Admiral Sir Robert Hill, Director-General of the Medical Department of the Navy, read an excellent paper upon Marine Hygiene. After pointing out to his audience that much of the organisation of sanitation afloat was similar to that required upon land, he emphasised the fact that marine hygiene necessarily differed in one important particular from land hygiene—only a limited allowance of sleeping and working space is available in a ship. The ventilation of ships, especially fighting ships, is a difficult problem, for armoured sides, decks, and bulkheads must be kept intact as far as possible, main watertight bulkheads must not be pierced below the main deck, and ventilation outlets or inlets, on or above the upper deck, must not interfere with the working of the guns, nor be placed within the area of their blast. The technical and constructional difficulties of the naval architect are therefore many when merely ventilation is in question. Three systems are employed in the Navy: (1) the Plenum system in which fresh air is forced into the space to be ventilated, thus driving out the foul air; (2) the exhaust system in which foul air is drawn out, thus sucking in fresh air; (3) the combined system, consisting of both artificial supply and exhaust. At present the Plenum system is generally used for living spaces, but the exhaust system for spaces in which are generated great heat, disagreeable odours, water vapour, or dangerous gases. The combined system is used for medical dressing stations and operating rooms. Means are provided for preventing draughts and for distributing air and warmth evenly. Air is warmed by passing between tubes heated by steam and a temperature of from 55–60° F. is aimed at. Speaking of the water-supply on board ship, Sir Robert Hill said that it had to be most strictly guarded, distilled water only being used when the ship

is at sea; when lying in harbour or in rivers ships are supplied by water-boats from the shore, which are designed and handled so as to reduce the possibility of pollution to a minimum. All water, moreover, supplied from the shore is treated with chloride of lime in the proportion of 30 gr. to 100 gallons. For ventilation and disinfection of ships formaldehyde vapour is used and also sulphurous acid. The former disinfectant was found of great service during the influenza epidemic of 1918. As to the health of the Grand Fleet during the war it was eminently satisfactory as regards pneumonia, enteric fever, and preventable diseases generally. The only serious epidemics were the two of influenza in the spring and autumn of 1918; in the former of these the death-rate was 0·03 per cent., in the latter 2·8 per cent., owing to the prevalence of broncho-pneumonia as a complication. We commend a study of this paper to our readers, for they will there learn to estimate aright the never ceasing watch which is kept by the Naval Medical Department over the health of its charges.

#### HOUSING SCHEMES.

WE learn that sites have been selected for the 400,000 houses which are to be built at some time or another to provide for the needs of the population, and the Ministry of Health is urging, in its magazine *Housing*, the necessity for speeding up. It is implied that local authorities are responsible for the delay, but we can imagine that local authorities are naturally chary about entering on schemes which must involve the spending of large sums of money. Economy appears to be the watchword of the Prime Minister and the Chancellor of the Exchequer, but we doubt whether economy will be realised in Government house-building after reading an article in *Housing* headed the Production Department. From this we learn that there are three problems in the production of a house: materials, labour, and transport. To manage these there is to be a production officer who will work in liaison with officials from the Ministry of Munitions for materials, the Ministry of Labour for labour, and the Ministry of Ways and Communications for transport. There will also be a regional advisory committee. We are not told whence the money is to come which all these bodies will assuredly demand, but we doubt whether local bodies will speed themselves up to get into liaison with this army of officials. In the meantime it is very desirable that the taxpayers, on whose pocket the cost of the housing is sure to fall, should be enlightened as to the manner in which the Government houses are to be built. For instance, we should like to know whether the water pipes will be run as much as possible away from the outer walls, or carefully packed if run down them, so as not to freeze in cold weather. Again, will the cut-off taps (if such are supplied, as they should be) be in a place where the tenant can get at them without risking: (a) setting the house on fire, (b) spoiling his clothes, (c) breaking his leg by having to scramble into mainly inaccessible places in a dark loft. Again, if there are electric bells will the bells be put where they can be seen and also easily reached. The members of the Housing Department of the Ministry of Health do live in houses, and have some idea as to what constitutes comfort and freedom from worry in a house be it ever so small. We should like to know that in the projected buildings all these things are being thought out,

for they are of immense medical importance. The medical interest in housing does not cease when ordinary questions as to site, aspect, and drainage have been satisfactorily answered.

#### THE ACTION OF ULTRA-VIOLET RAYS ON THE ACCESSORY FOOD FACTORS.

AN interesting differentiation of the accessory food factors appears in a paper by S. S. Zilva, published in the July number of the *Bio-Chemical Journal*. This investigation showed that the exposure of treated lemon juice to ultra-violet rays in neutral condition does not influence its antiscorbutic activity. Similarly the exposure of autolysed yeast juice for the same length of time does not impair its antineuritic potency; but butter exposed for eight hours to ultra-violet light undergoes a very noticeable change, and the fat-soluble A factor in it becomes inactivated. The moral of this is that butter should be kept in the dark, and it is well known also that light is a contributory factor in rendering butter rancid.

#### ANDREW CARNEGIE.

By the death of Andrew Carnegie, in his eighty-fourth year, a conspicuous figure passes from the ken of this world. Born of comparatively poor parents, who were in his childhood ruined by the introduction of the power loom in displacement of the hand loom, he arrived in America with his family in 1848. After passing through the stages of bobbin-boy in a cotton-mill, furnace-boy in a factory, telegraph operator, and various posts in the Pennsylvania Railway Company, he became, in 1863, superintendent of the line. He had both made money and acquired experience, and the enormous development of the iron industry which began after the American Civil War gave him his opportunity. He possessed to the full the faculty of using men, and though naturally kind-hearted and generous, business always came first. In 1873 he put £50,000 into an iron and steel company; 26 years later the business was sold for something over £90,000,000, Carnegie's share being more than a half. Although relentless in his methods of making money he gave away enormous sums, his total benefactions by 1908 being estimated at about £85,000,000, and most of this was devoted to organs, education, peace propaganda, and the Hero Fund. If his benefactions did not bring about all the benefits that he desired it was not for want of will, and his gift of £2,000,000 to Scottish universities is an example to be followed, for all the criticisms which have been showered on it. It is because of this gift that he may be regarded as a supporter of the cause of science. His mentality was curious, his gospel of wealth laid down strict theories as to the duties of wealth, yet, as the great Homestead strike showed in 1892, he was a bitter, even venomous, opponent of organised labour. If he did not live to see one of his ideals realised—namely, the union of Great Britain with the United States—yet he at least saw the two nations brought into more intimate relations than ever before. His other ideal, the abolition of war, received a rude shock in 1914, and while the conflict was being fought out he relapsed into complete seclusion. On the whole it may be said of him, that other men laboured and he entered into their labours, yet he tried his best to do good with wealth which in some ways had ominous origin.

## REGISTRAR-GENERAL'S DECENNIAL SUPPLEMENT (1901-1910).

### I.

IN Part III. of the recently issued supplement to his seventy-fifth annual report Sir Bernard Mallet contributes a volume which will certainly be welcomed by students of statistical science. This volume contains detailed statistics of natality as well as mortality in England and Wales during the ten years 1901-10, and forms part of a series of decennial reviews of which the first, published in 1864, related to the period 1851-60.

Although in some earlier years summaries of recent mortality had been issued from the General Register Office, Dr. William Farr decided in 1864 to inaugurate a regular system of decennial reviews in which the proportions, resting on the experience of a sufficient number of years, should deserve the confidence of statisticians. At the close of each subsequent decennium similar supplements have been issued, retaining to a large extent the essential features of the original volume. In this report the Registrar-General presents an interesting review of the whole series from 1851-60 onwards. He expresses regret at the late appearance of the work, but attributes the delay to the war, which has entailed depletion of the staff and imposed new and urgent duties upon those responsible for the production of this volume. The present supplement, like its several predecessors, deals with registration areas, which, except in the case of counties, are not coextensive with any territories used for public health or other administrative purposes. It is the last of its kind, the scheme designed for the next supplement being based on administrative in place of registration districts as the local units for tabulation.

#### *Natality, Legitimate and Illegitimate.*

The births in England and Wales during the ten years ended in 1910 numbered 9,298,209, of which 370,418 were born out of wedlock. There has been a creditable decrease of illegitimacy between 1871-80 and 1901-10, a decrease which is the more remarkable as it commenced whilst the legitimate birth-rate was still rising. Stated in terms of the living at all ages, the decennial birth-rate in the course of the last six decennia has varied from 35.4 in 1871-80 to 27.2 in 1901-10; but, calculated as it ought to be, in proportion to the numbers of women of child-bearing ages—i.e., from 15 to 45—the birth-rate shows a greater fall than when calculated on the aggregate population.

#### *Natural Increase of Population in Recent Decennia.*

The mean populations employed in this volume were calculated by the method described in the annual report for 1907, which is a modification of that used for the decennial supplement of 1891-1900. The results obtained by the two methods differ very slightly, the main principles in both cases being identical. The estimated mean population of England and Wales in the latest decennium was 34,180,202 persons, among whom females were in excess by more than a million.

The natural increase of the population by excess of births over deaths in each of the last six decennia is shown by a table from which it appears that the fall in the death-rate had almost exactly compensated for the fall in the birth-rate throughout the period from 1851-60 to 1901-10. But, during the latest decennium this balance has been upset, the further decline in the death-rate being insufficient to compensate for the fall in the birth-rate, even before the war. Dr. T. H. C. Stevenson gives reasons for believing that "these excesses of crude birth-rate over crude death-rate (which are of practical importance as measuring the rate of increase actually occurring) are the result in each case of two factors, the tendency towards reproduction or death, and the opportunities afforded by each population for the display of these tendencies."

#### *Deaths and Standardisation of Death-rates.*

The deaths registered in England and Wales during the decennium 1901-10 numbered 5,248,774, corresponding to a crude rate of 15.4 per 1000 living, which is the lowest recorded since the establishment of civil registration. From a table of male and female death-rates in the respective decennia it appears that mortality has fallen by 30 per cent. in the course of the last 60 years, the fall in 1901-10 being

much more rapid than in any previous decennium. For comparative purposes it has long been the Registrar-General's practice to express mortality in the form of "corrected death-rates"—i.e., rates "weighted" to allow for differences of sex and age in the population experiencing the observed mortality. These rates are now referred to as "standardised," the reasons for this change having been explained in the annual report for 1911. The enumerated population of England and Wales in 1901 has been retained as the standard in the present volume, and all standardised rates incidental to earlier decennia have been recalculated accordingly. From a useful table we learn that during the last half century a much greater decline has occurred in the mortality of females than in that of males at all ages from 15 upwards. This has had the effect of increasing the excess of mortality in the male sex which has been manifest at all adult ages from the earliest periods for which records are accessible. This excess has long been, and still is, very marked at age 45-55, when it amounts to 30 per cent. But the changes at some other ages are even more noteworthy. Thus, equality of mortality between the sexes at age 35-45 in 1841-50 has been converted into a male excess of 22 per cent. in 1901-10, and a female excess mortality of about 6 per cent. at ages 25-35 in 1841-50 has gradually been changed into a male excess of 17 per cent. in 1901-10. It is notorious that the number of females aged 20-25 has been overstated in the Census returns. And if such misstatement at this period did not apply equally to the returns of age at death, it would have the effect of reducing the recorded mortality of females at this age, and so, possibly, of converting a real deficiency into an apparent excess of male mortality. Nevertheless, there can be no doubt of the male excess in 1901-10, when it amounted to not less than 19 per cent. At ages 15-20 the pre-existing excess of female has during the last two decennia been converted into an excess of male mortality.

At age 5-10, on the other hand, female excess has during the same period replaced a pre-existing excess of male mortality. This is the only age-period at which the mortality of females has increased relatively to that of males. At age 10-15 the death-rate of females has been in excess throughout the seven decennia, though in 1871-80 practical equality was attained. It is particularly noteworthy that at every age-period from 5 to 25 years among males and from 5 to 35 years among females the mortality in 1901-10 was less than half that recorded 50 years previously—viz., in 1851-60. The decline in mortality in 1901-10 from that in the preceding decennium was shared by each sex at every age-group, the slight increase among young children experienced in 1891-1900 having given place to a decrease in 1901-10 amounting to 20 per cent.

#### *Mortality in Infancy and Early Childhood.*

An outstanding feature of the decennium under review is the substantial diminution in loss of life among young children, especially infants. The mortality of infants in their first year was equal to 128 per 1000 births, while that of children under 5 years was equal to 46 per 1000 living at that age. Both of these rates are the lowest recorded in any previous decennium. The fall in the mortality of the first year of life started about the beginning of this century. Infant mortality in the last quinquennium of the nineteenth century was as high as it had ever been since 1837, and had been slowly rising for 15 years. The remarkable fall since experienced commenced with the year 1902. The death-rate in the first five years of life, which had been stationary in the last three quinquennia of the nineteenth century, began to fall again with the first year of the new century. It has since maintained an almost parallel course with that of infant mortality, of which, naturally, it is largely composed.

It is noteworthy how closely the relative position of the English counties, as regards mortality in early life, corresponds to that of subsequent ages in the aggregate. The six counties with highest total mortality—viz., Stafford, West Riding, Glamorgan, Northumberland, Durham, and Lancaster—return also the highest mortality at ages under 5 years, almost in the same order, as well as furnishing five out of the six highest places in infant mortality. Evidently the environment which weeds out most of the weeklings in early life is also the most prejudicial to survival at later ages. A similar conclusion would be reached if comparison were made between *counties* instead of *counties* as above, and it seems to follow that measures

which preserve the lives of young children must generally promote the vitality of survivors likewise.

The distribution of mortality over each of the first five years of life is here discussed, both for the country at large and for the urban and rural groups of counties. The difference between urban and rural environment appears to influence the death-rate considerably more in the second and each of the three succeeding years of life than in the first. The urban excess, which is 30 per cent. in the first year after birth, grows to not less than 96 per cent. in the second and third years, after which it declines to 56 per cent. in the fifth year. This excess is at all ages much less due to the extent by which the urban rates exceed the average, than to that by which the rural rates fall below it; this, indeed, is natural, in view of the relative populations of the two groups. Among girls the favourable effect of rural environment is more perceptible than among boys at the earlier ages, but after the second year there is scarcely any difference in this respect. The death-rate of females, which is much below that of males in the first year after birth, gradually approximates to it in the next three years, and in the fifth year even slightly exceeds it, as it tends to do also in the two subsequent quinquennia of age. So considerable is the influence of environment on life and health during the second and third years of life that whilst in 1901-10 the mortality of the urban group of counties in the third year was practically identical with that at all ages together, that of the rural group was only two-thirds of the corresponding figure for that group at all ages. In childhood the difference between urban and rural mortality may be regarded as a rough indication of the comparative extent to which mortality generally is preventable. And thus the extreme importance is emphasised of safeguarding the health of children in the years intervening between infancy and compulsory school attendance—a matter which is now happily receiving the public attention which it deserves.

## THE PUBLIC SUPPLY OF VACCINE LYMPH.

A MEMORANDUM has been prepared by the Ministry of Health, for the use of the medical officer of health, in connexion with the supply and use of vaccine lymph for the vaccination or revaccination of persons who may have been exposed to small-pox infection. The Memorandum has been prepared for convenience of reference in consequence of a number of small outbreaks of small-pox that have occurred during recent months in which it was evident that the procedure to obtain vaccine lymph is not always fully understood. The Memorandum runs as follows:—

1. The importance of obtaining the prompt vaccination of persons who have been exposed to small-pox infection needs to be emphasised, as cases have recently occurred in which known contacts of small-pox cases have not been offered vaccination promptly and subsequently have developed small-pox.

2. It is the duty of the public vaccinator to vaccinate or revaccinate at the public expense persons in his district who apply to him for the purpose, and who have not previously been vaccinated or revaccinated within a period of ten years. Vaccination of small-pox contacts by the public vaccinator should therefore be regarded as the ordinary procedure when this can be arranged without causing delay. In this connexion it should be remembered that public vaccinators frequently have in their possession a recent supply of vaccine lymph ready for use. In any case, the medical officer of health is requested immediately to acquaint the public vaccinator and vaccination officer concerned when cases of small-pox come to his notice.

3. Vaccination of small-pox contacts may also be carried out by the medical officer of health without reference to the public vaccinator, and sometimes it is obviously the best course that these contacts should be vaccinated by him at once when the fact of exposure to infection has been discovered. The Local Government Board issued in 1917 the "Public Health (Small-pox Prevention) Regulations," which provided that: "The medical officer of health of any local authority may, on the occurrence of any case of small-pox and where the circumstances, in his opinion, so require and permit, perform vaccination or revaccination on any person who has come in contact with the infection and is willing to be vaccinated, and without charge to the said person."

4. Vaccine lymph from the Government Lymph Establishment will be supplied for this purpose to medical officers of health on application by letter, telegram, or telephone to the Government Lymph Establishment, Colindale Avenue, The Hyde, London, N.W. 9. Telegraphic address: "Defender," Hyde, London." Telephone No.: Kingsbury 41 (London District).

The next three sections of the Memorandum contain important counsel and information. The Government Lymph Establishment advise that lymph sent out by them should be used within a week of its receipt as an obvious precaution against unnecessary storing. An exception can be made in the case of ports in frequent communication with the continent if the medical officers of health of such ports communicate with the Establishment. It is also stated that lymph supplied to medical officers of health is for vaccinations performed by them, their assistants, or deputies, while arrangements for facilitating public vaccination in an affected district will continue to rest with the boards of guardians and public vaccinators. Medical officers of health, in vaccinating contacts, are enjoined to keep a dated record of vaccination, revaccination, and their results, with name, age, and address of the subject. Where Government lymph is employed the official reference number should be recorded, and lymph from supplies where no information concerning source is kept should not be employed.

The Memorandum quotes from a circular of the Local Government Board of Feb. 13th, 1917, the regulations referred to in its third paragraph, which run as follows:—

(a) Vaccination should at every stage be carried out with aseptic precautions, which should include the cleansing of the surface of the skin before vaccination, the use of sterilised instruments, and the protection of the vaccinated surface against extraneous infection both on the performance of the operation and on inspection of the results. Advice as to the precautions to be taken in this respect until the scabs have fallen and the arm has healed should always be given to the person vaccinated or, in the case of the vaccination of a child not more than 14 years of age, to the parent or other person having the custody of the child.

(b) In all ordinary cases of primary vaccination the vaccinator should aim at producing four separate good-sized vesicles or group of vesicles not less than half an inch from one another. The total area of vesiculation resulting from the vaccination should not be less than half a square inch.

(c) If any person vaccinated or revaccinated requires medical treatment in consequence of the vaccination or revaccination, the local authority should offer to provide such medical treatment as may be required.

(d) The local authority should arrange to pay to the medical officer of health such sum as is reasonable in respect of the extra work which he undertakes in pursuance of these regulations. For their guidance the Board may state that in their view the payment should be not less than 2s. 6d. for every vaccination or revaccination performed.

When a medical officer of health reports to the Ministry of Health a case of small-pox in his district (Article XIX. of the Local Government Board's General Order of Dec. 13th, 1910), it is desirable that he should add a note regarding the steps taken to secure the vaccination of contacts. Recent experience shows that it is important to bear in mind that inspectors or others concerned with the removal of small-pox cases or the disinfection of their clothing, and members of hospital staffs who at any time are likely to come into contact with a small-pox case, should at all times be well protected by revaccination, and should not take the risk of waiting to be vaccinated until exposure to infection has occurred.

**DROUGHT IN BELFAST.**—Like many other places in the United Kingdom Belfast is now feeling the effects of the continued drought. July is usually a wet month, but during July of 1919 rain to the extent of only 0·68 in. fell in nine days, the average for the previous 44 years being 2·80 in. during that month. Indeed, for the whole of the year 1919, up to July, the rainfall has been only 15·15 in., while the average is 20·51 in. All over Ulster the weather has been very dry; for example, in Warrenpoint, at the head of Carlingford Lough, there were only four days in July during which rain fell to the extent of 0·54 in., while in the same month of 1918 rain fell to the extent of 5·11 in. in 13 days. As a result farmers and water commissioners are becoming uneasy. In Belfast the water in store on July 31st was reduced to 1461 million gallons—that is, 340 million gallons less than at a corresponding date in last year. The supply has been already reduced, and it is announced that, if the weather continues, a still further reduction will be made.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Prevalence of Rabies in Paris and in the Department of the Seine and Oise.*

THE annals of the Pasteur Institute contain the annual report for 1918 of the Institute with respect to the treatment of rabies for the year. The tables affixed to the report make very instructive reading, for they display a great progression of cases of rabies observed and treated. The number of these cases amounts to 1803 for the year 1918, while the information collected by the antirabic service allows us to foresee that for 1919 the total will be still higher. In 1914 only 373 cases came under treatment. It is in the Department of the Seine and Oise that increase has been particularly marked. Before the war from this department only 30 cases of rabies came to the cognisance of the Institute each year. In 1918 there were 193 cases.

*Boric Acid in the Preservation of Food.*

The report by M. Lindet to a committee of the Health and Hygiene Department of the Seine calls attention to the increased employment of boric acid in connexion with food-stuffs, and dwells on the dangers which emerge for public health. Before the war such employment of boric acid was interdicted where not limited to small percentages in case of certain products. Severe proceedings have been taken against the manufacturers of soft cheese, who employ for preservative purposes a German speciality containing boric acid to a degree which renders the food dangerous to habitual consumers. The war suppressed the importation of this stuff and the cheeses grew better, but to-day there is a renewed danger, the incriminated substances, no doubt, coming into France by devious routes. Moreover, there is a sale now for the yolks of eggs, rare and costly delicacies, which have been preserved by boric acid, while butchers use borates to retard putrefaction of their wares, and so do those who sell fish and butter. Evidently the use of boric acid is not being controlled owing to the urgent food difficulties of the war. M. Lindet's report concludes with a demand for the return to the legal repression of these dangerous procedures.

*Æsthetic Surgery.*

Æsthetic surgery, or, as you call it, cosmetic surgery, continues to develop its territory. Two communications have already been received at the Academy of Medicine upon the correction of nasal deformities by surgical intervention within the nostrils and under the skin, the sections and sutures being carried on without any cicatricial result which is visible from without. More recently Dr. Passot has undertaken the cure of wrinkles. He had observed that when the skin in front and above the ear was pulled upon obliquely from below upwards and backwards effacement of many wrinkles took place, while folds due to laxity of the integument disappeared. His technique for obtaining these results consists of a little cutaneous resection under local anæsthesia at a site preferentially covered by the hair. The scalp is shaved before the operation, and cicatrices will be hidden by the growing hair. The operation, made with full aseptic precautions and followed by minute suturing, gives, he considers, excellent results, no trace of the proceeding remaining. For wrinkles on the forehead a similar operation is practised in the temporal region. The hair having been shaved previously, the cuts here are spindle-shaped. These little operations appear to have been followed with considerable success, particularly among women.

*Venous Tension and Varicose Veins.*

Dr. Mabile has made important advance in the diagnosis and treatment of varicose veins in employing the sphygmometer and the viscometer, in order to measure the blood-tension in venous system. This examination is made in the recumbent position, the leg being first horizontal and then vertical; then in the sitting position, the legs hanging down; and finally, in the standing position. The observation of the differential pressure measuring the deviation between the maximum and minimum pressures, and of the oscillometric index, allow venous troubles to be classified in three groups:—(1) Venous erethism, temporary troubles due to fatigue or to the great ingestion of liquid; (2) valvular

insufficiency; and (3) endocrine troubles. Each of these has its different characteristics. This procedure allows the fixing of rules for treatment: to the first category of cases massage is assigned, to the second surgical intervention with resection of the femoral vein, and to the third treatment by medicaments.

August 11th.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

*The Influenza Epidemic.*

FOR the last two months the feature of the epidemic in Victoria has been the steady level of morbidity and mortality. From 10 to 12 deaths daily occur for the whole State. The number of hospital patients is gradually diminishing. There are at present about 750 in public hospitals. In New South Wales the lifting of the restrictions soon after Easter was followed by an immediate, though not explosive, spread, just as happened in Victoria. During the past month in Sydney the spread has been very acute, and the death-rate has become very serious, although it is difficult to say what ratio it bears to the actual number of cases. Banks and public offices have been partly closed owing to shortage of staffs. There are at present 2000 hospital cases, and fear is expressed that further accommodation will have to be provided. The Government have not reapplied the restrictions as to masks or public assemblies, and the chief health officer for Sydney has expressed the opinion that no measures of public health are likely to be of any avail. In Brisbane the disease has appeared in epidemic form, but has never reached alarming proportions, although the death-roll already numbers some hundreds. In South Australia it appears to be smouldering. Tasmania still remains free, and owing to the shipping strike has practically been cut off completely from the mainland for the last month. Lord Jellicoe visited several Tasmanian harbours, but no communication was allowed with the shore.

*Returning Troops.*

Practically the last of the hospital cases from overseas have arrived in the hospital ship *Karoola*. The system of dealing with returning men in Victoria, or, as it is called, "finalising" them, has been brought to very smooth working. The men are brought straight from the transport to a depot where a number of medical boards are in waiting. The medical officers sit in groups of two and mark the men in three divisions. Those who have suffered no disability and are well are classed A and discharged forthwith. Those who have suffered disability but do not need treatment are B and are awarded a pension on the spot, which is subject to review in six months. Those who need treatment in hospital are sent to Caulfield Military Hospital; those who need out-patient attention or require a special examination to assess their pension rights, are referred to No. 5 A. G. H., now used only for out-patient cases. As many as 500 men are handled in an hour and a half by seven boards, and the system is popular with the men. The scene outside the depot where the relatives of the men are in waiting is one of considerable animation, and everyone inside works their hardest to pass the men out as rapidly as possible. Every man is examined by a dentist and given the right to six months' dental attention if needed, whether discharged or not. The Red Cross officials also give each man a parcel of underclothing.

*A Question of Ethics.*

An ethical question is attracting attention in Sydney. Professor D. A. Welsh, who occupies the chair of pathology in the University, recently wrote several articles over his own name in the *Sun*, a Sydney daily newspaper, on the subject of influenza. This constitutes a breach of the by-laws of the New South Wales branch of the British Medical Association, and the matter was brought to the notice of the local council. Professor Welsh wrote intimating that he would resign his membership of the branch, but the council replied that he could not do so unless he also resigned his membership of the British Medical Association. There the matter stands at present. Professor Welsh is one of the three members of the consultative council on influenza appointed by the Government in New South Wales.

*Medical Honours.*

Several well-known practitioners have received distinctions in the Birthday Honours. Sir J. C. Verco has been a leader in Adelaide for many years, and has held almost every position of professional distinction as a practitioner and teacher. Surgeon-General C. S. Ryan, of Melbourne, has received the honour of C.B.E. Dr. T. P. Dunhill receives a C.M.G.

*Eliza Hall Institute.*

The position of director of the Eliza Hall Institute of Research, which been established at the Melbourne Hospital by an endowment for that purpose, has been given to Dr. S. W. Patterson, who is a graduate of the Melbourne University, but has been for some years engaged in special study in London. Dr. Patterson served during the war with the rank of major in the R.A.M.C.

June 26th.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

*The Soldier's Life in India.*

REFERRING to the relief of the Territorials which is now proceeding, a leading Indian journal says: "Apart from their military services, one of the most important achievements of the Territorial in India has been his success in obtaining better conditions for soldiers in garrison. The old regular who happens to be in India to-day will admit the amenities of his life have been enormously increased. For much of this the new units will have to thank the Territorial officers and men who, having a 'divine discontent,' made it felt to good effect."

*Red Cross Work for the Afghan War.*

The Indian branch of the Joint War Committee of St. John and the Red Cross telegraphed within 24 hours of the outbreak of hostilities for supplies to be sent up to the front from the main dépôt at Bombay. Shortly afterwards the five Assistant Red Cross Commissioners, whose services had been obtained from the Commander-in-Chief, arrived at their bases at Rawal Pindi, Peshawar, Kohat, Bannu, and Quetta. Since then the committee have been receiving indents from them almost daily and have already sent up supplies valued at five lakhs of rupees (£33,000 sterling).

*Women's Medical Service.*

The Central Committee of the Countess of Dufferin's Fund for the junior branch of the Women's Medical Service for India announces that in selected cases promotion will be made from the junior to the senior branch of the Women's Medical Service. Such selection will be made from any grade, even the lowest, when the Selection Committee is convinced that promotion is deserved and a vacancy has occurred. Should the Central Committee consider that it would be in the interests of any of the members recommended for selection to proceed to Europe for post-graduate study financial assistance will be given to deserving members in their own and the public interest. In such cases definite courses of study will be laid down such as may from time to time be found suited to the requirements of India. It must, however, be understood that the number of vacancies in the senior Women's Medical Service is at present small, although it is hoped that the service may in the near future be augmented.

*Calcutta Ophthalmic Hospital.*

The absence of an efficient ophthalmic hospital in Calcutta has long been a reproach to Bengal. The existing hospital is inadequate and ill-equipped, and it has to serve not only the requirements of Bengal but of areas outside that province, patients coming from great distances to be treated. Just before the war the Government is understood to have purchased a site for a new hospital. The Indian press has been commenting on the subject in strong terms, and it suggests that what is wanting is a larger conception of the whole situation regarding the treatment of eye diseases in India and a more statesmanlike way of dealing with it.

*Beggars in Madras.*

An agitation is on foot in Madras to do something to control the large number of diseased beggars who infest the

streets. The Governor has just issued an appeal on behalf of the lepers, for whose suffering thousands much more ought to be done than has been achieved in the past; but until it is recognised as an offence instead of a legitimate profession to beg from every possible victim, the large army of those who exist by this means will prefer to pick up their living as hitherto.

*I.M.S. Officers from Ceylon.*

In response to the appeal recently made for recruits from Ceylon, upwards of 50 applications have been received from Ceylon doctors desirous of joining the Indian Medical Service. The number of Ceylon Government medical officers allowed to join the Indian service has not yet been decided on.

*Pilgrimage Sanitation.*

The Government of Bihar and Orissa have submitted to the Government of India a Bill to make better provision for the control and sanitation of places of pilgrimage in the province.

*Bombay Water-supply.*

A recent official report by the municipal hydraulic engineer stated that "if two consequent failures of the monsoon should occur before the water-supply is again increased, it will be absolutely necessary to stop all water supplied for trade purposes." The daily amount available for domestic supply during the last nine months has been only 22 gallons a head of the population.

July 20th.

## URBAN VITAL STATISTICS.

(Week ended August 9th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 9.0, 10.3, and 9.7 in the three preceding weeks, was again 9.7 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 9.5 per 1000, and coincided with that in the previous week, while among the remaining towns the rates ranged from 2.9 in Wimbledon, 3.0 in Willesden, and 3.5 in Ilford, to 15.5 in St. Helens, 16.2 in South Shields, and 16.5 in Stockton-on-Tees. The principal epidemic diseases caused 131 deaths, which corresponded to an annual rate of 0.4 per 1000, and included 53 from infantile diarrhoea, 35 from diphtheria, 21 from measles, 11 from whooping-cough, 7 from scarlet fever, and 3 from enteric fever. Diphtheria caused a death-rate of 1.0 in Bolton, 1.1 in Portsmouth, and 1.2 in St. Helens. There were 1547 cases of scarlet fever, 1092 of diphtheria, and 1 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1538, 1117, and 2 respectively at the end of the previous week. The causes of 25 deaths in the 96 towns were uncertified, of which 5 were registered in Liverpool, 4 in London, and 3 in Gateshead.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 10.6, 11.1, and 10.6 in the three preceding weeks, further declined to 10.0 per 1000. The 224 deaths in Glasgow corresponded to an annual rate of 10.4 per 1000, and included 9 from infantile diarrhoea, 4 from diphtheria, 3 from enteric fever, and 2 each from measles and whooping-cough. The 62 deaths in Edinburgh were equal to a rate of 9.6 per 1000, and included 1 each from whooping-cough and diphtheria.

*Irish Towns.*—The 99 deaths in Dublin corresponded to an annual rate of 12.7, or 0.9 per 1000 above that recorded in the previous week, and included 12 from infantile diarrhoea and 1 each from enteric fever and measles. The 73 deaths in Belfast were equal to a rate of 9.5 per 1000, and included 2 from infantile diarrhoea and 1 from scarlet fever.

*DONATIONS AND BEQUESTS.*—By the will of the late Sir Archibald Davis Dawney, of Cedars-road, Clapham Common, Mayor of Wandsworth, the testator has left, among other bequests, 5000 £1 shares in Messrs. Dawney and Sons, Ltd., each to King Edward's Hospital (Cardiff Infirmary) and the Putney Hospital, Lower Common, Putney; 500 shares to the Royal Hospital for Incurables; his premises known as Eddington, Barnet Wood-lane, Ashted, to the Putney Hospital; and No. 108, Penylan-road, Cardiff, to King Edward's Hospital (Cardiff Infirmary).

*FATALITY FROM CARRYING LOOSE MATCHES.*—At an inquest held by Mr. Ingleby Oddie on August 5th at Lambeth on the body of David Rothery, aged 17, employed by the Nugget Polish Company, a witness stated that he saw Rothery with his clothing alight. He turned the hose on him and put the flames out. Rothery's clothes were saturated with turpentine, and before his removal to the hospital he stated that he had stumbled over a barrel, when some loose matches in his pocket caught fire. A verdict of "Accidental death" was returned.

## Correspondence.

"Aud alteram partem."

## INTRAVENOUS INJECTIONS OF ANTIMONY TARTRATE IN BILHARZIASIS.

To the Editor of THE LANCET.

SIR,—Dr. Frank E. Taylor's series of ten cases of vesical bilharziasis treated successfully by antimony tartrate, as recorded in THE LANCET of August 9th, are very interesting because they are all British soldiers who contracted the disease in Egypt during the recent war. There must be hundreds of soldiers in this country similarly infected, and, in view of the fact that such cases if not cured will demand and receive pensions, it is of importance that this treatment should become known and scientifically carried out by keen and able observers. The treatment needs care and skill and some tenacity of purpose, for it demands, to ensure success, that the urine shall be examined microscopically every day of injection. But care, skill, and tenacity of purpose expended are amply repaid by the great interest of the developments which result and by the certainty of the cure.

Mr. J. R. Newlove and I reported at length<sup>1</sup> details of the treatment as carried out at the Khartoum Civil Hospital during the last two and a half years. Over 70 cases were included in that paper and we have watched the result of treatment in some cases for a period of over two years. The result has conclusively demonstrated the permanency of the cures.

With regard to the series of cases reported by Dr. Taylor I shall not be surprised if, in every case, ova reappear in the urine and with the ova hæmaturia (microscopic blood only perhaps) and some albuminuria. But supposing, as is most likely, ova do appear again in the urine of these cases this will not mean that the treatment has not been successful, for the ova are those already deposited by the worms before the course of treatment. They, naturally, are eliminated as foreign bodies, even after the death of the worms. In some of our cases dead ova were eliminated for two years after the course of injection. Further, if the ova which are eliminated after a total of 10 or 15 gr. of antimony tartrate have been injected be microscopically examined it will be found that they are *small, shrivelled, black*, and have lost their double contour, and that their contents are granular and do not show the outline of primitive organs. They are, in fact, dead, sterile, and incapable of harm.

Antimony tartrate not only kills the bilharzia worms in the portal circulation; it also acts directly on the ova already deposited in the bladder and rectum, and these ova, although they are eliminated in due course, are sterile—in fact, the patient has ceased to be a carrier of bilharzia disease. That the ova are sterilised by antimony tartrate is a fact more important than that the worms are killed. Prophylaxis is more important than the individual cure.

The case reported by Major R. G. Archibald and Major Arthur Innes<sup>2</sup> should never have been reported as a case of death from the treatment. He died of influenza pneumonia, as was shown by the post-mortem examination. I have written fully in reply to this paper.<sup>3</sup> Any fatty degeneration found by the authors in the organs was probably due to other causes—intestinal parasites, ankylostomum, tænia nana, or to bilharzia itself (it is a mistake to think that bilharzia acts as a mere mechanical agent and that the only effect is the physical one, the ova acting merely as foreign bodies; Ferguson and Fairley have both shown that bilharzia is more far-reaching in its effects). It has yet to be proved that antimony tartrate, given in doses necessary to cure bilharzia (25–30 gr.), gives rise to fatty degeneration, or, in fact, that its causes fatty degeneration at all. Other workers have recorded cases of bilharzia where 37 and even 67 gr. have been given, and, as Dr. Taylor states, very much larger doses have been given for trypanosomiasis and, I may add, for kala-azar, without any untoward result.

The suggestion of Major Archibald that the deaths which have occurred in cases of kala-azar where antimony tartrate

has been used are due to fat embolism needs a rather serious call on the imagination, for it is difficult to believe that microscopic fat, deposited in the cells of an organ, becomes dislodged and finds its way into the blood-vessels and so to the heart to form the embolus. So far as my experience goes, these cases of death in kala-azar are due to heart failure—e.g., an emaciated kala-azar patient after an injection tries to sit up in bed, or perhaps gets out of bed to urinate or defæcate in the absence of the attendant, and the resulting heart-strain is in itself sufficient to produce the fatal result in the later stages of the disease. In bilharzia the patient is not as a rule weak and this danger does not present itself.

For the information of practitioners who may wish to give this treatment a trial I append a list of references to papers of workers who have written on the subject of the antimony tartrate cure for bilharziasis.

## THE ORIGIN OF LIFE: THE WORK OF THE LATE CHARLTON BASTIAN.

To the Editor of THE LANCET.

SIR,—In my letter concerning the origin of life published in your issue of August 2nd I said, referring to Hon. H. Onslow's experiments, "I suggest that Mr. Onslow kept some of his 'white solution' tubes far too long—three years in some cases—before opening them and examining their contents." Mr. Onslow refers to this as a misrepresentation. I should be sorry to have misrepresented Mr. Onslow in any way in discussing his experiments or the results thereof, but my information was obtained solely from his own published report, contained in the Proceedings of the Royal Society, B 628, p. 268, wherein he seeks to prove—and does prove to the entire satisfaction of several persons—that my father was totally in error not only in regard to his facts, as recorded in his book, "The Origin of Life," but in regard to the necessary interpretation arising therefrom. Mr. Onslow states that 8 out of 10 tubes of his "white solution," cited as being typical examples of the whole series, were kept for 33½ months before they were opened. This is certainly too long, and in such circumstances the tubes could only contain, as they did, dead organisms.

Without quoting in extenso what is said in Mr. Onslow's report, I think any reader of it will acquit me of misrepresentation. I plead guilty only to a legitimate misunderstanding of this account of scientific experiments, which, by Mr. Onslow's own showing, is a very incomplete one, in parts somewhat vague. Furthermore, the experiments strike me as being open to criticism in some other respects, notably as regards the kind of glass used, which, to the best of my recollection, was not "hard German glass" but soft soda glass. I consider Mr. Onslow's conclusions should not be finally accepted as refuting the conclusions of my father which were based on such a prolonged, careful and systematic research. It is, perhaps, just as likely that Mr. Onslow's comparatively few negative results are open to as much criticism as the many alleged positive results obtained by my father and others. What work of this nature could be expected to be entirely free from error? In any case we are not in a position to judge as to the cogency of this or that series of experimental results unless we are put in possession of *all* the facts and are shown, by way of some help, photomicrographs of what was actually found in the experimental tubes—dead or alive.

It is for these reasons, and because I venture to think that sufficient evidence has not yet been produced to disprove the reality of archebiosis, that I would urge the necessity of my father's experiments, not only in archebiosis but also in

<sup>1</sup> Journal of Tropical Medicine and Hygiene, July 16th, 1919.<sup>2</sup> Ibid., April 1st, 1919.<sup>3</sup> Ibid., June 14th, 1919.

heterogenesis, being repeated in many different quarters by independent observers. It is only by these means that we may expect the ultimate truth to be revealed.

I am, Sir, yours faithfully,

W. BASTIAN,

Chesham Bois, August 10th, 1919.

Surgeon Commander, R.N.

To the Editor of THE LANCET.

SIR,—A word of explanation is needed in reply to M. Albert Mary's interesting letter in your issue of August 9th. The effects due to radioactivity are totally distinct from those produced by barium, strontium, calcium, manganese, or lead. For the latter precipitate in the course of time to the bottom of the test-tubes, whilst the former remain at the top. These disappear when heated or exposed to daylight, and reappear again when kept for some hours in the dark. They have all the properties of Mr. Emil Hatschek's vortices referred to in my previous letter of July 26th. Mr. Raphaël Dubois, as M. Mary is perhaps unaware, did not describe anything of the sort, and his observations refer merely to the "grosses vacuolides," which are undoubtedly not due to radioactivity. It is clear, therefore, that he did not, in the first instance at any rate, observe the bodies I have called radiobes, which I am convinced are due to radium and are totally distinct from his vacuolides, for they are much smaller and possess different properties. Furthermore, they are not vesicles, and are, on the other hand, too large to be bubbles of the emanation (as Sir William Ramsay suggested), the quantity of radium salt used being insufficient for this. The best results are obtained with the weak salt of radium chloride. Strong radium bromide almost obliterates the effect, probably owing to the heat evolved or other influence of the bombardment.

As I have already suggested, each  $\alpha$ -particle should give rise to a vortex in the "gel"; and as these particles are being continually projected in all directions a series of such bodies in "massed formations," ever moving forward, would endeavour to force their way out, and ultimately a scrimmage would ensue, when the group finally segregated; each half going its own way. I estimate on Sir Ernest Rutherford's most recent work on  $\alpha$ -particles<sup>1</sup> that the boundary would be about  $0.3\mu$ , the size I had found to be the maximum for radiobes.<sup>2</sup> This boundary formed by the  $\alpha$ -particles' vortices would be the nucleus which I have observed, whereas the outer boundary would be due to the fast-moving H-atoms which Rutherford and Marsden have found to be projected through the violent impact of the  $\alpha$ -particles with oxygen, nitrogen, carbon, and hydrogen. It is noteworthy, as it appears from their latest results, that the principal constituents of protoplasm—namely, H, C, N, and O—are the ones which are thus broken up by the  $\alpha$ -particles; heavier atoms not being so affected.

According to the "principle of relativity" now so much discussed by physicists, there should be a directional force as the resultant influence of all the  $\alpha$ -particles; for the effect of the earth's rotation would impart to these an unequal motion in different directions; an effect of about 0.4 per cent. This should give the aggregate of vortices so produced a tendency to evolve in one particular direction rather than another; and thus, perhaps, give us a physical analogue to the "élan vital" of living matter, to which hitherto there has been no clue, from physico-chemical considerations. My earlier experiments seemed to indicate something of the sort with radium, that could not be accounted for at the time; but I am investigating the matter further in the light of more recent facts on these lines. The suggestion, then, in my previous letter to you was that similar effects might be set going by purely catalytic actions, if  $\alpha$ -particles are emitted with sufficient violence in chemical reactions; and it is possible, in the light of these considerations, that Dr. Bastian's and M. Mary's synthetic corpuscles may owe their origin to this cause, which, whether it produces them or not, should thus give rise to others like them.

I am, Sir, yours faithfully,

Kingston Hill, August 9th, 1919.

J. BUTLER BURKE.

\* \* The original title of this correspondence indicated the question at issue to be the accuracy of the work of the late Charlton Bastian.—ED. L.

## TALENT AND MISCEGENATION.

To the Editor of THE LANCET.

SIR,—It is reported of one of the modern gladiators who, for good or evil, command to-day so much public attention and support, that he has in him a good deal of American Indian blood. The same was said of Longboat, a Marathon runner, as also of a musical comedy actress well known over here in the "nineties." But the coincidence of mixed race with distinction is not confined to those whom Aristotle would have called professors of the little arts. Onida was half French, Lettson of creole extraction. The late Watts Dunton's origin was always supposed to include a gypsy element. It is curious that Mr. W. B. Yeats, the noted poet, has a parentage exactly similar to that of the Brontës—namely, an Irish father and a Cornish mother. Rossetti was three-quarter English and one-quarter Italian. Freud, Ehrlich, Bergson, and Kerensky have, or had, plenty of Jewish blood. And one could go on in like fashion for a long time, overloading this letter with capitals and proper names. It seems a pity that the subject is not investigated more. There does exist a German work upon it, reviewed in the medical press of this country about a dozen years ago. Mr. Havelock Ellis, too, has touched it in his study of British genins. Of his 1030 persons of ability, 143 sprang from some degree of miscegenation, which is, perhaps, a high proportion for an island country, 97 being mixed British—i.e., of intermingled English, Irish, Scotch, or Welsh origin—and 46 mixed British and foreign. English-Irish was found to be the commonest of the former crosses, and of the latter English-French. Among the few women in the list about a third were of mixed race, the English-Irish combination again coming first. Mr. Ellis's qualification for inclusion in his study material was rather high, as a general thing a notice of at least three pages in the "Dictionary of National Biography." It is possible, however, that miscegenation tends to the production of various kinds of minor talent, too. In turning over the pages of a large encyclopædia, in reading obituary notices, in recalling persons of ability among ordinary acquaintances, one is apt to come upon the phenomenon under notice.

### Miscegenation in Theatrical Celebrities.

It is curious, again, on going through Mr. Ellis's detailed list, to have found that the celebrities of mixed blood include Garrick, Mrs. Siddons, Macready, the two Kembles, Helen Fancit, Kitty Clive, Barry Sullivan, and Kelly. Clearly there are here the flower of British acting. Five out of these nine owned continental strains of blood. Play-writers are numerous too—Marston, D'Urfey, Lillo, Killigrew, Vanbrugh, Beddoes, and Browning. No other calling was so strongly represented as actors and dramatists. The rest were mostly occupied with art or literature, there being only two men of science, and no inventors. This last is a little surprising. It had seemed possible that American inventiveness might have been traceable to the copious American miscegenation, that country being now "the jakes of Europe," as England, with doubtful correctness, was called by Defoe.

### How does Mixture of Race Originate Talent?

Several speculations are possible as to how the mixture of race originates talent. The simplest supposition, perhaps, is that the mere cross is without influence, persons of ability being more likely than others to travel and meet and marry foreigners, their offspring inheriting their talent. It may be so. The comparative lack of high grade talent (except, as already stated, inventiveness) in America seems to corroborate this view, for emigrants nowadays are not persons of eminent ability. Peter the Great took his Deptford paramour home with him and begat the elder Cozens, known widely as a painter in water-colours. The elder begat the younger Cozens, also a painter, whose works Constable described as being "all poetry." But why painting talent? We do not know that either Peter or the mother had any ability that way. We do know that Peter had other ability. Also that he showed atavistic traits—for instance, primitive savage callousness notable even in an absolute monarch of an uncivilised seventeenth-century people. Those of strong nerves may read how he conducted a mistress of his, a noblewoman, as far as the arms of the executioner, slipped round to the front for the final spectacle, picked up the head,

demonstrated rather competently—he was always interested in anatomy—to his courtiers the musculature surrounding the severed vertebra, turned it round, lightly kissed the lips, put it down again, and went off upon his business. This may suggest remotely another explanation. The crossing of breeds was shown by Darwin to lead to reversion or atavism, and atavistic traits of various kinds are common accompaniments of artistic talent.

Again, first crosses in domestic stock do seem to result in hardiness and good constitution, as in the mule or in poultry; mongrel dogs, too, are often more sagacious than pure-breds. Besides the instance given, many others exist of pugilists of mixed race: Jewish half-breeds, gypsy half-breeds, are frequent in the history of the ring. The many professional golfers from the Channel Islands may be a further example of physical ability caused by miscegenation, this territory having been alternately French and English for some centuries.

#### *The Dumas Family.*

In face of the history of the Dumas family it is hard to rule out the mere blending of race as the prime cause. Here miscegenation seems all-important, producing talent, indeed genius, out of nothing. An undistinguished French aristocrat meets an undistinguished Hayti negress wench. Their child is a prodigy of physical courage, development, and prowess. A noted cavalry leader, he can gallop at a grenadier, pluck him from the ground, and throw him across his saddle-horn. With other environment, say poverty in present-day America, this "Horatius Cocles of the Tyrol" would have been one of the half-breed boxers, who, although mostly Roumanian or Mexican or Scandinavian, for some reason call themselves by a true blue Anglo-Saxon name. Horatius's son, by an undistinguished woman, is Dumas père, the best story-teller pure and simple in the world. His son, again, by another out-cross, a mere Belgian milliner, is Dumas fils, the best playwright of latter-day France (in both note again the association with the stage).

#### *Generalisations.*

On this pedigree, certainly a slender foundation, it is possible to construct a theory of the origin of miscegenate talent. That, to begin with, the lowest form mostly results, mere physical aptitude, or histrionic ability, the lowest form of art—the production of histrionic capacity being how miscegenation helps up so the list of distinguished women, because acting is the only art in which women quite equal men. Then sometimes the original physical or histrionic talent may transmute in the succeeding generation into psychical or higher psychical, a professional cricketer begetting a novelist, an actor begetting a Wagner. But these generalisations grow dangerously top-heavy. The subject, not in the line of present-day thought, is likely to attract much interest before, say, the end of the century. Its Darwin may be some unorthodox scholar-biologist, roaming happily, his life through, from *Bibliothek* to *Bibliothek*. I am, Sir, yours faithfully,

August 4th, 1919

CADUCEUS.

### THE POSITION AND PAYMENT OF THE PENSIONS BOARDS.

*To the Editor of THE LANCET.*

SIR,—Dr. Lauriston E. Shaw propounds a scheme to relieve the temporary financial embarrassment of "partial" pensioners who break down. He does not know, it seems, that these cases are already provided for admirably or that the Medical Services Branch of the Ministry has given birth to a body of experts in assessment whose work is far from likely to bring blame upon our profession, as he suggests. A little practical knowledge would convince him that it is these experts rather than the well-cared-for pensioners who stand in need of sympathetic advocacy. On my hoard the senior members (engaged and paid by the session) hold responsible posts requiring daily attendance, special knowledge, and some administrative ability. Officially part-time, we are actually whole-time members, and yet if we are all ill or there is a bank or peace holiday our pay ceases. We have protested more than once, claiming pay proportionate to the nature and value of our work and to the cost of living, with security of tenure and right to a holiday. We have been told—our claim receives sympathy—the value of our work is recognised; if we will kindly carry on something may be

done some day, nobody is to blame except the Treasury. Meanwhile, by way of humour, perhaps, hatches of men paid more than ourselves and on the terms we ask, are sent to be trained by us for similar work in the provinces. We remain at our posts as much from interest and pride in our board—a model of organisation—as from loyalty to our president, to whom it owes its unique value for the pensioner and taxpayer. But we feel that we are entitled to relief from an unjustifiable financial anxiety—a relief that is essential if our work is to be continued at its present level of efficiency.

Your admirable leading article of August 2nd points out that the common policy of the profession is to serve humanity but carries a right to remuneration calculated to secure good service. The bare fact is that we are denied a living wage, and are suffering in consequence. The outlook is alarming. Is it the desire of the Treasury to reduce our families to the standard of living which the Ministry of Health has been set up to abolish? Are we to be a precedent upon which our profession will be made to suffer in the future? We should welcome investigation by any body standing for the ideals of our profession. I enclose my card with the name and address of my board for your use should any such body propose to accept the invitation, and would appeal especially to the medical Members of Parliament to assist us to prevent circumstances and the spreading spirit of discontent from forcing us unwillingly in a wrong direction.

I am, Sir, yours faithfully,

MEDICO.

August 10th, 1919.

### THE INCIDENCE OF TUBERCULOSIS AMONGST ASYLUM PATIENTS.

*To the Editor of THE LANCET.*

SIR,—The figures and conclusions given by Dr. F. A. Elkins and Dr. Hyslop Thomson in their valuable paper in your issue of August 9th will not surprise those acquainted with an essay on the frequency, causation, prevention, and treatment of phthisis pulmonalis in asylums for the insane, which was printed in the *Journal of Mental Science* for October, 1899. In this paper, however, any special liability of the insane to tuberculosis, apart from hereditary and environmental conditions, was ascribed rather to the shallowness and infrequency of the respiratory movements than to lowered tissue resistance. The conclusions reached in this essay were in 1901 entirely and handsomely endorsed by the report of a special commission of the Medico-Psychological Association, though the findings of this commission perhaps received somewhat less than their due meed owing to the fact that certain tables drawn up by the commissioners were afterwards shown to be not free from statistical error.

But no statistical or other error was ever shown to have had place in the original essay which provoked the appointment of the commission, and Dr. Elkins and Dr. Thomson now, by implication, have not only vindicated its conclusions but drawn attention to the consequences of neglect of its lessons. War has been responsible for much, but there is no reason why we should not now recognise that which was pointed out in 1899—namely, that "in the majority of cases in which phthisis leads to a fatal issue the disease is acquired in the asylum," and that aggregation, lack of ventilation, overcrowding, and a diet poor in fats, are each and all in measure responsible for the deplorable results.

I am, Sir, yours faithfully,

F. G. C.

London, W., August 10th, 1919.

Lieutenant-Colonel W. B. Edwards, C.B.E., R.A.M.C.; Lieutenant-Colonel J. E. H. Davies, D.S.O., R.A.M.C.; Lieutenant-Colonel D. Hepburn, C.M.G., R.A.M.C. (T.); and Colonel Sir Charles A. Ballance, K.C.M.G., C.B., M.V.O., A.M.S., have been appointed Knights of Grace of the Order of the Hospital of St. John of Jerusalem in England.

DEATH FROM STATUS LYPHATICUS.—At an inquest held by Mr. Wynne Baxter at Stepney on August 5th on the body of Eric Richardson, aged 3 years, who died while under an anæsthetic in the Poplar Hospital, it was stated that death was due to the existence of status lymphaticus. The coroner, having pointed out to the jury that the existence of this condition was not possible to discover before the administration of the anæsthetic, a verdict of "Death from misadventure" was returned.

## The Services.

### THE HONOURS LIST.

The following "statements of services" are announced for the awards recorded in *THE LANCET* of March 8th, 1919, p. 398. All are members of the R.A.M.C. except where otherwise stated:—

#### *Bar to the Distinguished Service Order.*

Capt. (acting Lieut.-Col.) JAMES HENRY FLETCHER, D.S.O., M.C., comd'g 35th Fld. Amb.—For most conspicuous gallantry and devotion to duty near Mametz, on August 26th, 1918, when in command of bearers. With another officer he crawled out under heavy machine-gun fire into "No Man's Land," dragged back two wounded bearers to a more sheltered spot, and after dressing them crawled back for assistance, organised two squads of bearers and brought the wounded men in under heavy fire; also two more wounded men found lying out. He set a splendid example to all serving under him.

Maj. (Temp. Lieut.-Col.) FRANCIS CORNELIUS SAMPSON, D.S.O., 91st Fld. Amb.—For exemplary devotion to duty on the night of Oct. 3rd/4th, 1918, at Le Baraque (north of St. Quentin) when this area was heavily bombed. This officer, regardless of personal danger, by his initiative and personal influence organised and accompanied relief parties and was instrumental in the rapid evacuation of the wounded. The bombing was very severe and the casualties heavy, there being 13 amongst the R.A.M.C. bearers alone; the actual number of killed exceeded 40.

#### *Distinguished Service Order.*

Capt. PATRICK AUGUSTINE ARDAGH, M.C., New Zealand M.C., att'd. 1st Bn. Auckland R.—For conspicuous gallantry and devotion to duty during an attack east of Masnières. Being forced to place his dressing station in a spot constantly shelled by the enemy for 36 hours, he continued to dress wounded while shells fell on the station. He attended, not only his own battalion wounded, but men of three other battalions, and worked continuously without sleep all the time. He displayed high courage and resource, and was the means of saving many lives.

Temp. Major CHARLES FRASER KNIGHT, 133rd Fld. Amb.—For conspicuous gallantry and devotion to duty in personally supervising the collection of wounded and visiting forward posts regularly under heavy shell fire. It was largely due to his energy and disregard of danger that the large number of wounded in his sector were successfully cleared. This was during the operation against the Hindenburg Line, east of Ronsoy, on Sept. 27th, 28th, and 29th, 1918.

Major LEONARD MAY, M.C., Aust. A.M.C., att'd. 11th Bn. Aust. Inf.—During the attack near Villers on Sept. 18th, 1918, he displayed great gallantry and devotion to duty whilst attending to the wounded. In consequence of his excellent organisation for clearing the wounded he was able to keep in touch with the advance, constantly moving his aid-post forward with the barrage, and maintaining liaison with the attacking companies throughout. He showed great disregard of danger under heavy artillery and machine-gun fire, and by his skill saved many lives.

Lieut.-Col. STANLEY PAULIN, 11th Fld. Amb., Can. A.M.C.—He was in charge of the evacuation of the brigade wounded in the operations about Cambrai. For the five days of that battle he worked day and night with very little rest. He was always leading and directing his men, and by his splendid example was responsible for the wonderful work done by those under him. His work under heavy shell and machine-gun fire was admirable.

#### *Second Bar to the Military Cross.*

Temp. Capt. GEORGE OLIVER FAIRCLOUGH ALLEY, M.C., att'd. 2nd Bn. R. Ir. Regt.—For conspicuous courage, energy, and initiative during the operations on Oct. 8th, 1918, in front of Niergnies. He followed up the battalion in the attack, dressing and evacuating wounded under heavy shelling, eventually establishing his aid-post right forward in a section of trench in the rear of the front line. Here he dressed and evacuated wounded, not only of his own battalion and brigade, but of battalions operating on the right and left flanks. Throughout the day he behaved splendidly, and by his fine devotion to duty saved many lives (M.C. gazetted June 4th, 1917).

Lieut. (Temp. Capt.) WILLIAM JOHN KNIGHT, M.C., att'd. 89th Fld. Amb.—During the operations east of Ypres from Sept. 28th to Oct. 3rd, 1918, he was in charge of the stretcher-bearers attached to a brigade. He led his bearers in the rear of the attacking infantry, dressing the wounded as they fell, and seeing that every case was carried away from the battlefield. During the whole of the advance he showed an utter contempt for danger, dressing the wounded under shell, machine gun, and rifle fire. Later, when the advance came to a standstill, he established touch with all the regimental medical officers and personally conducted the evacuation of wounded from the R.A.P.'s. On many occasions he went forward with stretcher squads to bring back wounded to the R.A.P.'s. He displayed great gallantry throughout and did admirable work.

Temp. Capt. (acting Major) MAURICE ALOYSIUS POWER, M.C., att'd. 148th Fld. Amb.—For conspicuous gallantry and devotion to duty whilst in charge of bearers during the operations on Niergnies on Oct. 8th, 1918. He personally followed the attacking troops to the final objective, establishing bearer relay posts en route, all the while utterly regardless of personal danger, though exposed to heavy enemy shell fire. His skilful organisation of the evacuation of wounded, and his maintenance of touch with all battalion medical officers, ensured the speedy evacuation of casualties. He set a splendid example to all ranks under his command.

#### *Bar to the Military Cross.*

Capt. (acting Major) JOHN BERNARD CAVENAGH, M.C., att'd. 113th Fld. Amb.—On Oct. 1st, 1918, when the advanced dressing station, Cambrai, was shelled, he went out to see about his men and ordered them under cover quite regardless of his own safety. On this occasion he was slightly wounded, but made no mention of it. Again, during the period from Oct. 11th-15th, when his advanced dressing station at Douvrin was being shelled, he displayed great coolness and courage. Following on this, while advanced dressing stations were in turn established at Berclau, Provin, Camphin, Les Croquet, Templeuve,

Bachy, Rumes, and Faintignies, he displayed great initiative and daring in keeping in close touch with the infantry. It was chiefly due to his sound judgment and coolness during the most trying circumstances that all the wounded and sick were so successfully evacuated.

Temp. Capt. FREDERICK ORLANDO CLARKE, M.C., att'd. 149th Fld. Amb.—For great gallantry and devotion to duty. During the operations against the village of Niergnies on Oct. 8th, 1918, when his aid-post was established in a dug-out at the Slag Heap, he observed two men lying out in the open about 50 yards off. Though a heavy bombardment at the time was on, he at once called for volunteers and, regardless of his own safety, went out and dressed them, and helped to carry them in. During this time one of the men was killed. It was undoubtedly owing to the gallant conduct of this officer that the man's life was saved.

Temp. Capt. CLAUDE NORMAN COAD, M.C., 74th Fld. Amb.—For great gallantry and devotion to duty when in charge of bearers during heavy fighting on Oct. 11th between Avesnes and St. Aubert. It was due to his fine personal example and total disregard of danger that over 400 casualties were evacuated on that day. He carried on his work often in front of the forward posts under heavy artillery and machine-gun fire until all the casualties had been brought back.

Capt. (acting Major) THOMAS FREDERICK CORKILL, M.C., att'd. 139th Fld. Amb.—While acting as officer in charge of forward bearers during the operations from Sept. 29th to Oct. 3rd, 1918, south-east of Ypres, he not only showed great resource in dealing with difficult evacuation to advanced dressing station, but a total disregard of danger. He personally frequently visited all posts at all times, both night and day, with most untiring energy and courage.

Temp. Capt. (acting Major) JOHN EDGAR DAVIES, M.C., 131st Fld. Amb.—For conspicuous gallantry and devotion to duty at Englefontaine on Oct. 25th, 1918. Hearing that there were over 1000 civilians in the captured town, he volunteered to go into it, interview the Mayor, and make the necessary arrangements for the distribution of smoke helmets. He entered the town under heavy bombardment and made his way to the cellar occupied by the Mayor through streets swept by enemy machine-gun fire. Several casualties occurred on the way up to a support battalion, and these he attended to and removed to safety.

Capt. FRANKLIN FLETCHER DUNHAM, M.C., Can. A.M.C., att'd. No. 5 Fld. Amb.—During operations about Neuville Vitasse, August 26th, 27th, and 28th, 1918, for conspicuous gallantry and devotion to duty. He organised stretcher parties under heavy shell fire, and located and dressed many wounded. On the 28th the stretcher-bearers under him moved practically with the infantry, and he personally directed the clearing of wounded from "No Man's Land" in daylight, under heavy machine-gun fire. His initiative and coolness were the means of saving many lives.

Capt. (acting Major) FRÉDÉRIC GAMM, M.C., att'd. 2/3rd (Home Counties) Fld. Amb., T.F.—During the attacks and counter-attacks near Peiziers from Sept. 22nd to 24th, 1918, when it was found impossible to obtain in the village a suitable spot for an advanced dressing station, he took up an ambulance car and used it as a dressing-room, working under constant shell fire all the time. His boldness and devotion to duty undoubtedly resulted in the saving of many lives and the mitigation of much suffering.

Capt. (acting Major) WILLIAM CLAVERING HARTGILL, M.C., 55th Fld. Amb.—For conspicuous gallantry and devotion to duty when supervising the evacuation of brigade casualties during the attack on Ronsoy, Sept. 18th, 1918. He early established his various posts and went forward and assisted in clearing wounded of his own and other brigades under heavy machine-gun and shell fire. He worked unceasingly, and it was greatly owing to the co-ordination of the arrangements and his personal supervision that casualties were cleared in a markedly efficient and speedy manner. Throughout he has done fine work.

Capt. (Temp. Major) ROBERT ALEXANDER HEPPLER, M.C., att'd. 28th Fld. Amb.—For conspicuous gallantry and devotion to duty during the operations at Roulers, Menin Road, and Leffeghem, Sept. 25th to Oct. 5th, 1918. As officer in charge of bearers he worked incessantly day and night, personally keeping in touch with the battalions in spite of shell and machine-gun fire; he never once lost touch with the regimental medical officers, evacuating the wounded with the utmost rapidity, thereby saving numerous lives.

Temp. Capt. (acting Major) BENJAMIN KNOWLES, M.C., att'd. 88th Fld. Amb., T.F.—For conspicuous gallantry and initiative in charge of stretcher-bearers during operations east of Ypres from Sept. 28th to Oct. 3rd, 1918. He led his stretcher-bearers following a barrage during the attack and organised relays for his men along the road of evacuation. Later he visited regimental aid-posts, often under heavy fire, and several times took up ambulance cars to casualties, carrying them away under fire. For six whole days he superintended the evacuation of wounded from the forward areas, and it was due to his great energy and disregard of personal danger that the wounded were evacuated without a hitch.

Temp. Capt. ALEXANDER CAMPBELL WHITE KNOX, M.C., att'd. 2nd Bn. R. Suss. R.—For conspicuous gallantry and devotion to duty throughout the operations north and south of the river d'Oignon from Sept. 18th to 24th, 1918. As medical officer of the battalion he organised and supervised the evacuation of the wounded in the most perfect manner despite shell fire and gas. Besides superintending the work at the regimental aid-post he personally supervised the work of the stretcher-bearers with the leading waves of the assaulting troops. Owing to his energy and personal supervision every wounded man was attended to and evacuated without delay. He did fine work.

Temp. Capt. (acting Major) HAROLD DUNMORE LANE, M.C., att'd. 1st N. Mid. Fld. Amb. (T.F.)—For conspicuous gallantry and devotion to duty. On Oct. 3rd, 1918, during the attack on Ramcourt and Wiancourt, he, who had already done magnificent work during the capture of Bellenglise on Sept. 29th, 1918, and since that date had worked unceasingly under heavy fire, pushed forward through the enemy's barrage, and, although wounded, continued to search for and dress wounded under heavy shell and machine-gun fire. By his absolute disregard of danger he set a splendid example to the men serving under him.

Capt. JOHN SHAW MACKAY, M.C., 12th Fld. Amb., Aust. A.M.C.—For conspicuous gallantry and devotion to duty on Sept. 18th, 1918, south of Le Verguier. He moved forward with his bearers closely in rear of advancing battalions and under heavy machine-gun and shell fire, and by absolute disregard of his own personal safety

was able to keep in close contact with brigade R.M.O.'s. By this action the wounded were evacuated in the quickest possible manner, all congestion at regimental aid-posts was prevented, and undoubtedly many lives were saved.

Temp. Capt. JAMES DAVID MACKINNON, M.C., attd. 4th Bn. Liverpool R.—During the operations on Sept. 29th and Oct. 10th/11th, 1918, at Villers Gislain and Le Cateau, he displayed consistent and conspicuous gallantry in attending to wounded under heavy fire, and saved many lives. His example of coolness and devotion to duty was very fine.

Capt. (acting Major) WILLIAM ARCHIBALD MILLER, D.S.O., M.C., attd. No. 6 Fld. Amb.—For conspicuous gallantry and devotion to duty from Sept. 27th to Sept. 29th, 1918, when in charge of stretcher-bearers during the advance from the Canal du Nord to the Canal de St. Quentin. He worked for three days without rest, and repeatedly led his stretcher-bearers to the front line, exposing himself to direct fire from enemy machine-gun posts. Especially on Sept. 28th, he led his bearers across the canal in close touch with the infantry, and brought back wounded through intense machine-gun and shell barrage. By his fine behaviour he saved the lives of many men.

Capt. LAUREL COLE PALMER, M.C., 13th Fld. Amb., Can. A.M.C.—In the operations before Cambrai he was in charge of stretcher-bearer squads from Sept. 27th to Sept. 30th, 1918. During this period he had absolutely no rest day or night, and was constantly under heavy shell fire; and on the 28th he personally brought up field ambulance squads, and carried out the wounded from in front of the front line under heavy shell and machine-gun fire. His untiring energy and disregard of personal danger were admirable.

Capt. JOSEPH GREGOR SHAW, M.C., 12th Fld. Amb., Can. A.M.C.—During operations near Cambrai from Sept. 25th to Oct. 1st, 1918, he was in charge of a party of stretcher-bearers clearing the 12th Canadian Infantry Brigade. He went for four days practically without sleep, during which time he was constantly superintending clearing operations in the vicinity of the regimental aid-posts. After two days, his senior officer having been gassed, the total responsibility devolved upon him. During this time, while constantly exposed to shell and machine-gun fire, his conduct was splendid, and he was the means of saving the lives of many wounded.

Capt. (acting Major) JAMES CALVERT SPENCE, M.C., attached 34th Fld. Amb.—For conspicuous gallantry and devotion to duty while in command of a bearer division, during the attack on Oisy-le-Verger and the subsequent operations from Sept. 28th to Oct. 2nd, 1918. In addition to handling his bearers with marked skill and initiative, he reconnoitred and selected sites for regimental aid-posts under heavy fire. Throughout the operations he showed untiring energy and complete disregard of danger. His fine leading of bearers on several occasions through heavy barrages enabled the wounded to be rapidly cleared, and undoubtedly resulted in the saving of many lives.

Capt. DONALD GEORGE KENNEDY TURNBULL, M.C., 11th Fld. Amb., Can. A.M.C.—During the recent operations before Cambrai, Sept. 29th, 1918, it was reported that there were still a great many wounded out in front of the regimental aid-posts of another brigade. He at once proceeded up the line with all available bearers, and under heavy fire investigated the conditions as to wounded. He got them all out so that none were left during the night of Sept. 29/30th, thus assisting materially in preventing deaths from exposure.

#### The Military Cross.

Temp. Capt. (acting Major) JOHN RICHARD PERCY ALLIN, 90th Fld. Amb.—For conspicuous gallantry and devotion to duty in charge of bearers on Sept. 29th, 1918, and following days. On the 29th, during the advance, he made his way through Lehaucourt to Le Trouquet despite severe shell and machine-gun fire. He promptly organised the evacuation of the wounded, and by his fine example and energy secured the rapid evacuation of over 250 casualties.

Capt. ALAN FENON ARGUE, Can. A.M.C., attd. 87th Can. Bn., Quebec R.—For conspicuous gallantry and devotion to duty, Sept. 2nd/3rd, 1918, at the Dury-Arras sector. During the attack he accompanied the battalion during its advance under very heavy fire, and established his first-aid post in a trench close to the front line reached by the battalion, and continuously during the day and night worked without any rest and under constant fire. Later, he went to the assistance of a wounded officer under heavy shell fire, dressed his wounds, and remained with him until he died in his arms. Throughout he behaved admirably.

Temp. Capt. (acting Major) BASIL WILLIAM ARMSTRONG, attd. 100th Fld. Amb.—For conspicuous gallantry and devotion to duty. During the fighting around Forenville and Seranvillers on Oct. 8th, 1918, he was in charge of the bearers clearing casualties of an infantry brigade. He constantly visited all the regimental aid-posts, having to pass along roads and tracks subjected to very heavy machine-gun fire throughout the whole day. All his work was done in the open, and by his energy, disregard of danger, and skilful organisation he succeeded in evacuating all the wounded in a very short time.

Capt. FREDERICK GRANT BANTING, 13th Fld. Amb., Can. A.M.C.—Near Haynecourt on Sept. 28th, 1918, when the medical officer of the 46th Canadian Battalion was wounded, he immediately proceeded forward through intense shell fire to reach the battalion. Several of his men were wounded, and he, neglecting his own safety, stopped to attend to them. While doing this he was wounded himself and was sent out notwithstanding his plea to be left at the front. His energy and pluck were of a very high order.

Capt. JAMES HAROLD BLAIR, C.A.M.C., attd. 72nd Bn. Brit. Col. R.—For conspicuous gallantry and devotion to duty during the Bourlon Wood operations before Cambrai from Sept. 27th to Oct. 1st, 1918. During the attack on Sept. 27th he rushed ahead under heavy fire and rendered immediate medical attention to all wounded in the vicinity. During the attack on the 29th he followed the attacking troops closely and dressed the wounded as he went forward, and formed the enemy prisoners into stretcher parties. Immediately after the town of Sancourt was captured he established a regimental aid-post there and continued to work under heavy fire. His work throughout was of the highest order.

Capt. EDWIN JOHN BRADLEY, attd. 1/3rd (N. Mid.) Fld. Amb., T.F.—He was in charge of the bearers during the attack on the St. Quentin Canal on Sept. 29th, 1918, and displayed great gallantry and initiative. He went forward and sought a position for an advanced dressing station in Bellenglise when it was being heavily shelled by the

enemy, and finally organised collecting and relay posts on a route farther north. His dispositions were most skilful and the rapid evacuation of the wounded was mainly due to the exertions of this officer.

Capt. MILLS GILLESPIE BROWN, Can. A.M.C., attd. 85th Can. Bn. Nova Scotia R.—For conspicuous gallantry and devotion to duty during the Bourlon Wood operations before Cambrai. On Sept. 27th, 1918, he advanced with the attacking wave from the assembly position, and attended wounded in the open under constant machine-gun and shell fire. He established his regimental aid-post in an open trench, no other place being available. Later, after his assistant was killed beside him and his sergeant wounded, he continued his work with absolute coolness and outstanding devotion to duty. He behaved splendidly throughout and saved many lives.

Capt. EDWIN THOMAS CATO, Aust. A.M.C., attd. 1st Bn. Aust. Infy.—In the operations near Hargicourt from Sept. 18th–21st, 1918, he showed untiring energy and devotion to duty in his care of the wounded, particularly on Sept. 21st, when in order to give early attention he established his aid-post in an open trench which was under shell fire and moved about the area continually, dressing wounded in shell holes and open country. By his disregard for personal safety and his cheerful confidence he set a splendid example to all.

Capt. HERBERT TROUGHTON CHATFIELD, attd. No. 6 Fld. Amb.—For conspicuous gallantry and devotion to duty from Sept. 27th to Sept. 29th, 1918, when in charge of stretcher-bearers. He frequently led his parties through machine-gun and shell fire to bring in wounded. He succeeded in keeping in close touch with the infantry throughout the advance to and the crossing of the St. Quentin Canal near Noyelles. By his fine conduct and example he was instrumental in saving many lives.

Temp. Capt. THOMAS CLAPPERTON, 141st Fld. Amb.—For conspicuous gallantry and devotion to duty during the attack on the Hindenburg Line on Sept. 29th, 1918. Throughout the day he repeatedly conducted bearers to the most exposed parts of the line to search for casualties. Though his advanced bearer post at Berthaucourt was heavily shelled he succeeded by his promptitude and energy in getting his wounded away without further casualties. His fine work was the means of saving many lives.

Capt. (acting Major) HUBERT ROY DIVE, 1/2nd Mtd. Bde., Fld. Amb., attd. 230th Fld. Amb.—On Sept. 21st, 1918, at Templeux le Guerard, when in charge of evacuation of casualties from the front line, he worked incessantly without rest under intense shell fire, exposing himself in the most fearless manner when bringing in casualties. He showed a very fine example of devotion to duty, and the successful evacuation was entirely due to his personal gallantry and initiative. He has been superintending the evacuation from the front line continuously since Sept. 2nd, and during all this period has shown the greatest zeal and resource.

Temp. Capt. ROBERT DONALD, attd. 35th Fld. Amb.—For conspicuous gallantry and devotion to duty on Sept. 27th, 1918, during the advance on Epinoy. He dressed cases in the open all day under fire, and established a chain of aid-posts as the infantry advanced. It was solely due to his unflinching zeal, his initiative and absolute disregard for personal safety, that a most difficult front-line evacuation was carried out with the utmost rapidity.

Capt. LEWIS HAYES FRASER, Can. A.M.C., attd. R. Can. Horse Arty.—On Oct. 10th, 1918, near Le Cateau, when a battery commander was reported badly wounded at the observation post, this officer went forward some 1500 yards through heavy fire to attend him. He arrived at the observation post just after the enemy barrage came down on it. Having attended to the battery commander he went out of the trench and crawled about under the heavy barrage for nearly an hour attending to wounded infantry. He showed great gallantry and devotion to duty.

Temp. Capt. WILLIAM BALFOUR GOURLAY (N. Russia).—Throughout the period Oct. 7th–15th, 1918, he showed exceptional devotion to duty in the care of the sick and wounded in the village of Borok, under frequent shell fire and several infantry attacks. His hospital at Borok had twice to be moved owing to fires caused by shelling; and though worn out by want of sleep and hard work he attended to the evacuation of the wounded when the troops moved back from the village, marching with them for a long distance and helping to ease them over bad roads under difficult circumstances. He set a fine example throughout of unselfish endurance in the performance of his duties.

Temp. Capt. NORMAN FRANKISH GRAHAM, attd. 6th Bn. Lond. R.—Near Maricourt, during the operations of August 26th, 27th, 28th, and 31st, 1918, this officer showed the greatest courage and devotion to duty. On three occasions, when the battalion to which he was attached moved forward, he immediately followed behind the battalion and established his regimental aid-post close up to the line, tending and superintending the collection of wounded under very heavy shell fire. He so organised the stretcher-bearer parties, largely using prisoners for this task, that the wounded were evacuated with a minimum of delay and discomfort. He was twice slightly wounded but carried on.

Capt. GERALD WALLACE GRANT, 4th Fld. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty near Vis-en-Artois on August 27th/28th, 1918. He was in charge of 15 squads of bearers, and throughout the whole operations superintended the clearing of casualties under almost continuous fire from the area allotted to him. On the 27th he led his squads in advance of the infantry position, and under machine-gun fire succeeded in removing from shell holes several badly wounded men to the collecting posts, whence they could be evacuated. He set a splendid example to those under him.

Temp. Capt. RICHARD PERROTT HADDEN, 103rd Fld. Amb., attd. 152nd Bde., R.F.A.—For conspicuous gallantry and devotion to duty when some transport came under heavy howitzer fire near Toubrielen on Oct. 8th, 1918. He went straight to the place through heavy shelling to attend to a wounded man, and by his prompt action and disregard of danger probably saved the man's life.

Capt. ALBERT ROBERT HAGERMAN, Can. A.M.C., attd. 78th Can. Bn., Manitoba R.—For conspicuous gallantry and devotion to duty during the Bourlon Wood operations before Cambrai. On Sept. 27th, 1918, he followed close behind the attacking infantry and established a regimental aid-post in the open under heavy shelling and dressed wounded under heavy machine-gun fire. On Sept. 29th he established a dressing station in a forward trench, and for two days he worked unceasingly under shell fire in this position, dressing hundreds of wounded. He did admirable work.

Capt. JAMES MANN HENDERSON, Aust. A.M.C., attd. 12th Bn. Aust. Infy.—During the attack near Jeancourt on Sept. 18th, 1918, he established his regimental aid-post immediately in rear of the jumping-off place and attended to the wounded of his and of a supporting battalion under heavy shell fire in an exposed position. As the attack progressed he moved forward and treated large numbers of casualties in the open. By his energy, disregard of danger, and clever organisation, he relieved a great deal of suffering, and throughout set a splendid example to those under him.

Temp. Capt. ALEXANDER HUNTER, attd. 63rd Divl. Eng.—During the operations on Niergnies on Oct. 8th, 1918, whilst attached to the advanced dressing station, when the advanced dressing station was being heavily shelled he went out to attend to some wounded. On his way he was knocked down by the explosion of a gas shell, but although severely burned he continued to attend to the wounded, displaying a remarkable coolness and utter disregard to personal danger. He refused to be evacuated and remained on duty until relief.

Temp. Capt. WILLIAM BOYD JACK, attd. 5th Bn. Leic. R., T.F.—For conspicuous gallantry and devotion to duty during the attack on Pontuet on the morning of Sept. 24th, 1918. His regimental aid-post was situated in a valley which was shelled consistently with gas and high-explosive shell. He had no dug-out and his work was entirely in the open. From 5 A.M. till 3 A.M. the following morning he worked unceasingly, entirely regardless of danger, and his fine conduct saved many lives.

Temp. Capt. MATTHEW JAMES JOHNSTON.—During an air raid at St. Omer on the evening of May 30th, 1918, four men had been buried at the Caserne d'Albret in the debris of part of the building which had been destroyed by bombs. He arrived immediately with an ambulance, and, in spite of the fact that the enemy planes were still overhead, set to work at once to effect a rescue. This had to be done in the dark, but the men were got out alive, and only one of them subsequently died. Other bombs were dropped near by whilst the work of rescue by this officer was still proceeding. On this, as on many other similar occasions, the conduct of this officer was very gallant.

Capt. CHARLES TERRELL LEWIS, Can. A.M.C., attd. 10th Bde. Can. F.A.—For gallantry and devotion to duty. On August 29th, 1918, during the operations along the Arras-Cambrai road, two gun pits were set on fire by hostile shells. An ammunition dump was exploded and several men wounded. He hastened to the spot and dressed the wounded and removed them to a dressing station. Throughout the whole operations he was untiring in his efforts to afford immediate medical attention to the wounded, many times under severe fire.

Temp. Capt. CHARLES WILLIAM BERRY LITTLEJOHN, 140th Fld. Amb.—For great gallantry and initiative in the operations south-east of Ypres from Sept. 28th to Oct. 4th, 1918. During this period he was in command of forward stretcher bearers, and it was solely due to his energy and dash that close touch was kept with battalions and their wounded promptly evacuated. He exposed himself freely to sniping, machine-gun and shell fire to get at the wounded of not only his own brigade but of other divisions, and by his fine conduct saved many lives.

Temp. Capt. ALFRED MASON, attd. 229th Fld. Amb.—Near Moislains and Hargicourt, Sept. 2nd/25th, 1918. While in charge of the bearer division working in front of the advanced dressing station he was unceasing in his efforts on behalf of the wounded. Although his area was on many occasions subject to very severe shell fire, and although he was for some days himself ill, he succeeded through sheer gallantry and devotion to duty in maintaining touch with the regimental aid-posts continuously during the advance, thereby securing the rapid evacuation of the wounded. His work was admirable.

Capt. HARRY CLARKE MOSES, Can. A.M.C., attd. No. 5 Fld. Amb.—For conspicuous gallantry and devotion to duty in charge of the advanced post of the right sector during operations round Neuville, Vitasse, Wancourt, and Cherisy, August 26th/27th, 1918. He was exposed to frequent enemy shelling, bombing, and machine-gun fire from aeroplanes, and when a shell exploded among a number of wounded awaiting evacuation he directed the adjustment of the masks on the wounded and succeeded in protecting them from all effects of the gas.

Lieut. WILLIAM PERCIVAL NELSON, attd. 128th Bn. Lond. R.—At Rumillies, on Oct. 8th, 1918, for gallantry and devotion to duty. During a very severe bombardment of both artillery and machine guns he constantly went out to the help of the wounded, attending them with utter disregard for danger, and was the means of saving several lives and alleviating a great deal of suffering. He has at all times set a striking example by his fearlessness and devotion to duty.

Capt. JOHN ARCHIBALD NICHOLSON, attd. 1st Bn. Sea. Hghrs. (Egypt).—For most gallant conduct and devotion to duty near Tabor on Sept. 20th, 1918. He moved about in the open under a heavy machine-gun fire to dress the wounded and bring them to a place of safety. Though casualties were very heavy, he continued to perform his duties with the greatest calmness and disregard of danger. He set a very fine example of devotion to duty and showed great courage.

Capt. KENNETH CLAUD PURNELL, Aust. A.M.C., attd. 11th Bde. Aust. Fld. Arty.—For conspicuous gallantry and marked devotion to duty during the attack on the Hindenburg line, south of Vendhuile on Sept. 29th, 1918. He dressed the wounded under very heavy shell fire, and organised a stretcher party, and conducted them to the battery positions, and by his personal and untiring efforts assisted in getting them to the nearest dressing station, a distance of about 1000 yards, and still under heavy fire. Throughout the day he worked splendidly.

Capt. ALLAN MELROSE PURVES, Aust. A.M.C., attd. 2nd Tunnel. Coy., Aust. Engrs.—On Sept. 29th, 1918, during the operations against the Hindenburg line, in the neighbourhood of Bellicourt, he formed an aid-post in a forward position. At this point the enemy put down a very heavy barrage which lasted about six hours and caused heavy casualties amongst the road party and the infantry in the vicinity. The whole of this time he attended to the wounded in the open, showing great gallantry and devotion to duty, and undoubtedly saved many lives.

Temp. Capt. EDWARD ROGERSON, attd. 2nd Bn. K.R.R.C.—For gallantry and devotion to duty east of Malsmeys on Sept. 18th, 1918, and during the operations of Sept. 24th/25th. On Sept. 18th he attended to and bandaged wounded men under heavy machine-gun fire. His actions undoubtedly saved many lives. During the heavy shelling of our positions on Sept. 24th/25th he was conspicuous for his utter disregard of danger while carrying out his duties, and throughout the operations he set a splendid example to those under him.

Temp. Capt. JAMES SCOTT, attd. 12th Bn. March. R.—On Oct. 12th, 1918, in front of Neuville, under heavy and accurate shell fire out in the open, he dressed the wounded without cessation. His cool courage under fire and his speed and skill, combined with his energy in keeping the stretcher-bearers going and in working eight enemy squads, saved many lives. He worked untiringly, and showed such spirit as inspired all who came near him.

Temp. Capt. THOMAS MCCALL SELLAR, attd. 118th Bn. Lond. R.—During the period August 28th to Sept. 6th, 1918, the battalion was continually in offensive action. Most of the stretcher-bearers became casualties. Throughout this time he worked with such untiring energy and marked gallantry that the regimental aid-post was constantly in touch with the attacking troops, and wounded were got back to the aid-post by his continually organising and leading forward small parties of bearers under heavy fire.

Capt. (acting Major) ARTHUR LEONARD SHEARWOOD, attd. 33rd Fld. Amb.—For conspicuous gallantry and devotion to duty on Sept. 27th/28th, 1918, during and after the attack on Oisy-le-Verger and Epino, when in charge of the evacuation of the wounded from the divisional front by motor ambulance. He worked for 36 hours unceasingly, visiting forward positions and establishing car-posts, under shell fire. His initiative and skill in carrying out these dispositions and his complete disregard for personal danger and fine example to all those under his command saved many lives and rendered the evacuation a complete success.

Capt. GEORGE ALEXANDER SMITH, Can. A.M.C., attd. 47th Can. Bn. W. Ont. R.—For conspicuous gallantry and devotion to duty during the operations in front of Cambrai from Sept. 27th/29th, 1918. He followed the battalion closely throughout the operations, showed great energy, and dressed many cases under heavy shell fire, working out in the open with practically no shelter. He set a very fine example to those under him.

Capt. CLIFFORD HALLIDAY KERR SMITH, attd. 14th Bn. K.O.S.B., T.F.—During the enemy attack on Mœuvres on Sept. 17th, 1918, this officer, when informed that there were many serious cases lying out requiring immediate attention, went forward in face of a very heavy artillery, rifle, and machine-gun fire and gave them his personal attention. As those urgent cases could not have been brought to the regimental aid-post in time for the necessary attention, this officer, by his prompt action and fearless devotion to duty, was undoubtedly the means of saving many lives of men in this battalion.

Capt. JOHN STIRLING, attd. H.Q. 12th Bde. R.F.A.—On August 26th, 1918, north of Maricourt, hearing that D 112th Brigade was being heavily shelled by the enemy, he immediately went to the battery and attended the wounded. Again, near Moislains, on Sept. 9th, 1918, when battalions were suffering casualties from enemy long-range guns, he went to them and attended their wounded. His gallantry and devotion to duty on numerous occasions have been most marked.

Capt. JOSEPH TOWNSEND STIRLING, 11th Fld. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. During the attack on Bourlon Wood on Sept. 27th, 1918, he dressed wounded in the open in the vicinity, under heavy shelling and machine-gun fire. Again, on Sept. 29th, when one of his men was killed and several others seriously wounded, he went to their assistance, got them dressed, and carried to safety.

Capt. RICHARD CHAPMAN WELDON, Can. A.M.C., attd. 2nd Can. Motor M.G. Bde.—While in action east of Arras on August 25th, 1918, at Jig-Saw Wood and Artillery Hill, he was in charge of the regimental aid-post, where he showed great gallantry and devotion to duty. The heavy and continuous shell fire made the work at the aid-post both heavy and difficult, entailing constant work for 36 hours without rest.

Temp. Capt. GEORGE BURKETT WILKINSON, 28th Fld. Amb.—On the night of Oct. 3rd/4th, 1918, at Waterdamhoek, he was in charge of advanced dressing station. Everyone had left the village on account of intense shelling. As wounded continued to come in he carried on dressing and evacuating wounded regardless of the risk he ran till the advanced dressing station was closed down. He showed great courage and devotion to duty.

#### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. E. W. P. V. Marriott retires on retired pay.

Capt. W. C. Hartgill relinquishes the acting rank of Major.

Temp. Capt. J. McP. MacKinnon to be Lieutenant and to be temporary Captain.

Lieut. (temp. Capt.) T. C. Bowlie to be Captain.

Temp. Lieut. H. C. Hinwood to be temporary Captain.

Officers relinquishing their commissions:—Temp. Lieut.-Col. J. F. Woodyatt (on ceasing to be in charge of Halifax War Hospital, and retains the rank of Lieutenant-Colonel); Temp. Hon. Lieut.-Col. W. J. Richard (on ceasing to be employed at the Merryflats War Hospital, and retains the honorary rank of Lieutenant-Colonel); Temporary Captains retaining rank of Captain: M. A. McKeever, W. P. Over, B. J. Hackett, J. A. G. Sparrow, J. N. Donnellan, J. A. N. Scott, E. E. Frazer, F. J. Wheeler, J. A. MacLeod; Temp. Lieut. C. O. Miller (retains the rank of Lieutenant).

#### Canadian Army Medical Corps.

Temp. Lieut.-Col. (acting Col.) T. C. D. Bedell to be temporary Colonel.

Temp. Major W. J. McAlister to be acting Lieutenant-Colonel while in command C.C.O.H., Matlock, Bath.

Temp. Majors (acting Lieut.-Cols.) R. M. Filson and E. A. Neff relinquish the acting rank of Lieutenant-Colonel.

The undermentioned temporary Captains (acting Majors) relinquishing the acting rank of Major: A. M. Yeates, J. N. Taylor, H. C. Allison, M. G. Thomson.

The undermentioned temporary Captains (acting Majors) to be temporary Majors: P. D. Saylor, H. C. Davis, D. J. Millar.

The undermentioned retire in the British Isles: Temp. Col. W. L. Watt; Temp. Lieut.-Cols. S. R. Harrison, E. L. Pope; Hon. Major I. D. Carson; Temp. Majors A. B. Walker, S. G. Ross, D. J. Cochrane, H. W. Whytock; Temp. Capts. H. C. Watson, V. D. Davidson, J. W. Dorsey, J. E. C. Henderson, M. G. Thomson, W. E. Jones, O. E. Kennedy, F. A. O'Kelly, G. W. M. Smith, T. G. Macdonald, R. G. Moffat, L. C. Reid, M. Krolik, T. Campbell, T. D. Wheeler, F. B. Sharp, R. MacKinnay, J. L. Poirier, J. W. Begg, G. B. Ferguson, D. Smith, R. F. Price, H. G. McCarthy, W. C. Lowry, M. F. D. Graham, V. K. O'Gorman, H. J. G. Geggie, B. Cohen. Temp. Hon. Capt. A. V. Whipple.

*Canadian Army Dental Corps.*

Temp. Major G. N. Briggs retires in the British Isles.

*South African Medical Corps.*

Temp. Capt. E. L. Reid relinquishes his commission and retains the rank of Captain.

**TERRITORIAL FORCE.**

Lieut.-Col. (acting Col.) H. Collinson relinquishes the acting rank of Colonel on vacating the appointment of Assistant Director of Medical Services.

Majors (acting Lieut.-Cols.) A. W. Moore, J. Wood, and D. H. Weir relinquish the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Cpts. (acting Lieut.-Cols.) H. H. B. Cunningham, W. Brown, and F. G. Dobson relinquish the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Capt. (acting Lieut.-Col.) L. D. B. Cogan to be Assistant Director of Medical Services, and to be acting Colonel whilst so employed.

Cpts. (acting Majors) F. E. Stokes, J. W. Thomson, A. L. Heiser, C. S. P. Black, J. W. McIntosh, and A. E. Ironside relinquish the acting rank of Major on ceasing to be specially employed.

Capt. H. H. B. Cunningham to be a Deputy Assistant Director of Medical Services, and to be acting Major whilst so employed.

1st London General Hospital: Lieut.-Col. Sir Anthony A. Bowlby, K.C.M.G., K.C.V.O., C.B., is retired and is granted the honorary rank of Major-General.

4th Northern General Hospital: Major (acting Lieut.-Col.) F. S. Genney relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

1st London Sanitary Company: Lieuts. J. Buckland and W. H. S. Dunn to be Captains.

1st Eastern General Hospital: Capt. P. N. B. Odgers is restored to the establishment.

3rd Western General Hospital: Capt. (acting Major) R. C. Elsworth relinquishes the acting rank of Major on ceasing to be specially employed.

**ROYAL AIR FORCE.**

*Medical Branch.*—Lieut.-Col. H. E. South (Fleet-Surgeon, R.N.) relinquishes his commission on ceasing to be employed.

Capt. (acting Major) C. J. G. Taylor and Capt. T. H. James are transferred to the unemployed list.

*Dental Branch.*—G. Packman is granted a temporary commission as Captain.

P. E. Bernard and R. H. More are granted temporary commissions as Lieutenants.

**INDIA AND THE INDIAN MEDICAL SERVICE.**

Lieut.-Col. J. Jackson, C.I.E., to be Colonel.

The King has approved the retirement of Lieut.-Col. A. H. Nott and Major D. S. A. O'Keefe.

Lieut.-Col. J. Stevenson, C.I.E., is retiring from the appointment of Principal of the Government College, Lahore. Capt. C. E. R. Norman resigns the service. Lieut.-Col. W. Vonne, Civil Surgeon, Cawnpore, has been granted leave, and Dr. C. A. Fuller officiates as Civil Surgeon, Cawnpore, during his absence. The Secretary of State for India has appointed Mr. Nibhatan Dhar to the Indian Educational Service as Professor of Physical and Inorganic Chemistry, Muir Central College, Allahabad. Capt. R. B. Lloyd, Imperial Serologist, has been appointed Chemical Examiner to the Government of Burma.

## Medical News.

THE death is announced of Dr. William Smith Greenfield, F.R.S. Edin., at the age of 73, who was Emeritus Professor of Pathology and Clinical Medicine, Edinburgh University, from 1881 to 1912.

UNIVERSITY OF LONDON.—At the Second Examination for medical degrees (Part I.) held recently the following candidates were successful:—

Francis Glen Allan, St. Thomas's Hosp.; Katharine Margaret Andrew, Newnham College; Joseph Atkin and Philip Bernard Atkinson, King's College; Grace Lily Austin, University College; Maud Kirkdale Baden-Powell, London School of Medicine for Women; Judah Samuel Benzery, University College; William Claude Morpott Berridge, St. Thomas's Hosp.; Mark Bersinski, Middlesex Hosp.; Hilda Alice Bond and Gwendolyn Jane Brooke, University College; Grace Emily Budge, London School of Medicine for Women; Helen Bumstead, King's College; Lily Clarkson Butler and Hilda Louisa Byett, London School of Medicine for Women; Dorothy Maude Campbell-Meiklejohn and Fanny Louise Cattle, University College; Gladys Maud Clarke and Marian Bertha Coleman, London School of Medicine for Women; Arthur Basil Cooper, St. Paul's School; William Leigh Spencer Cox and Eleanor Mildred Creak, University College; Hilda Mary Cunningham, London School of Medicine for Women; Donald Vaughan Davies, St. Paul's School; Morris Denman, Middlesex Hosp.; Barbara Joan Edwards, University of Birmingham; David Glyn Mason Edwards and Alfred Claude Mitchell Elman, University College; Brenda Harks English, London School of Medicine for Women; Charles Walter Evans, University College; George Morgan Evans, University College, Cardiff; Shafik Abd-el-Malek Fam, King's College; Mary Dorothy Fletcher, University College; Louis Fogelman, Guy's Hospital; Annie Foner, University College; Mary Elizabeth Fox, London School of Medicine for Women; Emily Lorna Franklin and Labib Ghabrial, King's College; Laura Phoebe Gibson, Lady Margaret Hall, Oxford; Cecil Percy Roderick Gibson, St. Thomas's Hosp.; Winefride Mary Gibson, Victoria Tutorial College; Horace Philip Goldsmith, University

College; Dorothy Eva Gray, London School of Medicine for Women; John Griffiths, University College, Cardiff; Aaron Gullorteln, London Hosp.; Margaret Constance Nool Hadley and Samuel Halperin, University College; James Rowland Hamerton, St. Bartholomew's Hosp.; Marjorie Florence Hayward and Barbara Joan Hilek, London School of Medicine for Women; Norman Gray Hill, London Hosp.; Gwynedd Hugh-Jones, London School of Medicine for Women; Robert Hunt Cooke, St. Bartholomew's Hosp.; Morris Jablonsky, King's College; Douglas James Tendon Jeans, Guy's Hosp.; Harry Victor Mainwaring Jones, St. Thomas's Hosp.; Robert Owen Jones, Middlesex Hosp.; Norman Adams Jory, St. Bartholomew's Hosp.; Jean Pierre Kies, St. Thomas's Hosp.; Alfred Charles King, London Hosp.; Charlotte Anne Kingdon, London School of Medicine for Women; Isaac Kinsler, St. Bartholomew's Hosp.; Charles Henry Landau, London Hosp.; Miriam Annabella Lawson, London School of Medicine for Women; Charles Emile Marie Joseph Libert, King's College; \*Edith Treveling Marshall, London School of Medicine for Women; Doris Ivy Mart, University College; Annie Pearce Martin, London School of Medicine for Women; Ysobel Maisie Howard Martin, Newnham College; Lucy Margaret Theodora Masterman and Margarethe Mautner, London School of Medicine for Women; Alan Aird Moncrieff, Middlesex Hosp.; Thomas Walter Morgan, University College, Cardiff; Richard Murchison Morris, London Hosp.; Herman Mould, University College; Ethel Murgatroyd, Newnham College; Frances Louisa Nichol, London School of Medicine for Women; Albert Boswell Nutt, University of Sheffield; Herbert Leslie Oldershaw, St. Bartholomew's Hosp.; Guan Yong Oon; University College; Beryl Palmer-Jones, University College, Cardiff; Emily Constance Noel Paterson, Newnham College; Dorothy Edith Peake, London School of Medicine for Women; Cyril Morgan Pearce, St. Bartholomew's Hosp.; Herbert John Plowright, Guy's Hosp.; Kathleen Mary Potter, University of Leeds; Violet Alice Quilleay and Alysoun Hurndall Rowntree, London School of Medicine for Women; Dorothy Stuart Russell, Girton College; George Drury Shaw and Thomas Archibald Shaw, Guy's Hosp.; Elizabeth Shlouden, King's College; Walter Roworth Spurrell, Guy's Hosp.; Betty Stainer, King's College; Edith Emily Stephens, Hilda North Stoessiger, and Margaret Swete, London School of Medicine for Women; Selwyn Edward Tanner, University College, Cardiff; Robert Wise Holden Thicker, St. Bartholomew's Hosp.; Maurice Auvache Townshend, University College; John Rutherford Tree, Middlesex Hosp.; Olga Frances Tregelles, London School of Medicine for Women; Thomas Fenemore Waring, London Hosp.; Reginald Lawson Waterfield, Guy's Hosp.; Lewis John Watkins University College, Cardiff, and private study; Constance Clara Maude Watson, King's College and Charing Cross Hosp.; Hilda Marion Weber, University College; Henry John William Jennings Westlake, Guy's Hospital; Edward Lincoln Williams, London Hosp.; and Esther Wingate and Isabelle Joan Woodhouse, London School of Medicine for Women.

\* Awarded a mark of distinction.

## Parliamentary Intelligence.

**NOTES ON CURRENT TOPICS.****WAR PENSIONS (ADMINISTRATIVE PROVISIONS) BILL.**

THE House went into Committee on Thursday, August 7th, on the War Pensions (Administrative Provisions) Bill.

*The Right of Appeal.*

On the motion "that this be the Schedule of the Bill,"

Mr. HOGGE complained that many of the men who were wounded in 1914-15 had not even an appeal against the assessment of the Medical Board. There was no medical referee in those days attached to the Local War Pensions Committee to which any of these men could appeal. He wanted to know if the appeal set up in Clause 8 of this Bill enabled any man who was eligible for a pension from the first date on which men were being wounded to go to this tribunal? This was an extraordinarily important point.

Sir JAMES CRAIG said it was the desire and duty of the Pensions Minister to see that the responsibility of passing men on to the Ministry of Labour rested with the medical advisers. Consequently, the desire of Mr. HOGGE was adequately met. No pensioner left the auspices of the Pensions Ministry until he was certified by their own medical staff to be absolutely fit to undertake the training which the Ministry of Labour proposed to give him. As to an appeal to a superior class of medical board, the door was by no means closed, but he could not pledge the Minister without having first consulted him.

The Committee Stage was concluded, and the Bill was reported to the House and read a third time.

**HOUSE OF COMMONS.**

WEDNESDAY, AUGUST 6TH.

*Hospital Arrangements in India.*

Colonel YATE asked the Secretary for India whether he could make any statement as to the amelioration of the hospital arrangements for the sick and wounded in the operations on the North-West Frontier of India; whether he was aware that one officers' hospital was so badly equipped that the patients had to use their shaving mugs

as drinking cups and tumblers; that no casualty lists were issued for more than a month subsequent to May 17th; and even wives were not officially informed of their husbands' deaths and were left to hear of it from other sources.—Mr. MONTAGU replied: As regards the first part of the question, I would refer my honourable and gallant friend to the very full statement which I have made in answer to another question of his [summarised in THE LANCET of last week]. The second part is covered by the request which I have already addressed to the Government of India for a report on the hospital referred to. It is not the case, so far as I am aware, that no casualty lists were published for more than a month subsequent to May 17th. Reports of casualties are communicated to the War Office as they are received by the India Office and are published by the former. Apart from publication, reports of casualties are immediately communicated by the India Office to the next-of-kin in all cases in which the names of the next-of-kin have been registered. If the honourable and gallant Member will inform me what are the cases to which he refers in the last part of his question I will have inquiry made.

Colonel YATE: I refer to the publication by the Government of India. I would ask with regard to the statement in yesterday's full statement which is referred to that the scale of equipment of Indian general hospitals has been reviewed and that arrangements for providing additional equipment are in progress does not show that the shortage brought to light by the Mesopotamia Commission has not yet been remedied in India, and that the pernicious report of Lord Nicholson and Sir William Meyer, which caused Lord Crewe to limit the expenditure on the Indian Army to £19,500,000 is still operating, and—

The SPEAKER: The honourable and gallant Member is making an argumentative speech.

#### *Hospital Carriers for Russia.*

Lieutenant-Commander KENWORTHY asked the First Lord of the Admiralty whether he was aware of the fact that six hospital carriers had been sent to North Russia for service on the River Dwina which could not ascend that river owing to their excessive draught; whether, in consequence, the arrangements for transporting wounded might be insufficient should heavy casualties be inflicted on our forces; and whether all possible steps were being taken to send out smaller carriers for wounded with all dispatch.—Dr. MACNAMARA (Secretary to the Admiralty) replied: The six hospital carriers referred to are six paddle steamers which were fitted out temporarily owing to the unavoidable delay on passage from Mesopotamia of vessels of smaller draught. They were the shallowest draught craft available at the time, and but for the abnormally low river would have been entirely suitable for the service. I am advised that adequate craft are now available at Archangel, and should more be required others are on their way.

#### *Public Health Research.*

Mr. WATERSON asked the Prime Minister whether the Minister of Health would throw wide open the door of research to all new ideas and methods, so far as the promotion of health was concerned.—Dr. ADDISON replied: I have been asked to answer this question. It is certainly the intention of the Ministry of Health to utilise every possible means for promoting the health of the people in co-operation with the Medical Research Committee and otherwise, and including in particular the investigation of the causes of disease and the encouragement of research, with an open mind for the reception of new ideas and methods.

#### *Medical Arrangements in Russia.*

Mr. RAWLINSON asked the Secretary for War if he would state how many hospital ships were now being used for the troops in North Russia; and whether an adequate supply of doctors, nurses, and hospital requirements had now reached our troops.—Mr. CHURCHILL replied: Two hospital ships are being used to evacuate patients from the military hospitals in North Russia. An adequate supply of doctors and hospital requirements are present at both Archangel and Murmansk. Six British nurses are doing duty in the hospital at Murmansk. There are no British nurses stationed at Archangel.

#### *Venereal Disease.*

Major WARING asked the Secretary for War whether he was aware that patients undergoing treatment for venereal disease in certain military hospitals in this country were permitted to move freely in populous districts every afternoon; and would he issue instructions that these infected persons should be confined to the precincts of the hospital throughout their period of treatment.—Mr. CHURCHILL replied: Patients undergoing treatment for venereal disease in military hospitals are not permitted to move freely, as suggested in the first part of my honourable and gallant friend's question. Except under very exceptional circumstances patients who are in a condition to spread infection are not granted leave from the hospital.

#### *Food for Patients in Sanatoriums.*

Mr. GRATTAN DOYLE asked the Minister of Health whether his attention had been called to the complaints that many tuberculosis patients in sanatoriums and similar institutions under the control of local authorities still suffered from the severe régime imposed by the war and food control as to food and nourishment; and whether he would cause such inquiries and alterations to be made as would ensure to such patients every consideration and help.—Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: I am aware that complaints have been made from time to time in respect of food and other matters in sanatoriums and similar institutions, and I am now inquiring into a particular case which has just been brought to my notice. I am advised that where the official dietary scales are properly carried out they are found suitable, but if the honourable Member will give me the details of any particular place where he has information that the food is inadequate, I will gladly have it investigated and reported upon.

THURSDAY, AUGUST 7TH.

#### *Filthy Streets and the Public Health.*

Major C. W. LOWTHER asked the Minister of Health whether he was aware of the dirty condition of the streets in the neighbourhood of Paddington, and whether he would take steps to cause the streets in question to be thoroughly disinfected with a view to preventing the propagation of disease.—Major ASTOR replied: My right honourable friend has no official representations on the subject, but in view of what has otherwise come to his knowledge he is in communication with the local authority with a view to considering what steps it may be desirable to take to safeguard the health of the people.

Colonel YATE: Is the right honourable gentleman in communication with the Kensington authorities, where the situation is very serious?—Major ASTOR: Yes, my right honourable friend has been in touch with Kensington for some time, and I understand that seven vans are collecting refuse in Kensington and that there will be 20 on the streets to-morrow.

#### *Breaches of Discipline at Warlingham Hospital.*

Sir STUART COATS asked the Secretary for War whether on Peace Day it was necessary, in answer to an urgent summons, to send a detachment of troops in motor lorries, with a machine-gun, from the Guards' barracks at Caterham to suppress a serious riot at the military hospital for venereal diseases at Warlingham; and whether he was now in a position to state what steps he was taking to prevent in future the recurrence of such breaches of discipline.—Mr. CHURCHILL replied: I am informed that there has never been a riot at the military hospital at Warlingham. A number of patients were, or had been, absent without leave on the night July 18th-19th, and to prevent additional men leaving the hospital a detachment from the Guards' Depot was sent on the morning of the 19th. No machine-gun accompanied the troops. The detachment of Guards was relieved the next day by other troops, who are still there. The breaches of discipline have been, and are being, dealt with in the ordinary course, and 20 men are now awaiting trial by district court-martial in connexion with the occurrence.

#### *Nurses at Archangel.*

Mr. JODRELL asked the Secretary for War if there were any British nurses in the port and town of Archangel; and, if so, how many, and when did they arrive.—Mr. CHURCHILL replied: There are at present no British women nurses in the port and town of Archangel. A matron and 13 sisters were, however, on duty on a hospital ship which was stationed at Archangel from Nov. 2nd till June 2nd last, when the ship returned with them to this country. The hospital ship returned to Archangel on July 7th with one matron and ten sisters and left again on the 28th with the nursing staff on board.

#### *Small-pox and the Italian Expeditionary Force.*

Mr. WATERSON asked the Secretary for War if he could state how many men who went to Italy in the spring of 1918 were vaccinated against small-pox.—Mr. CHURCHILL replied: Two cases of small-pox were reported as occurring among the troops of the Italian Expeditionary Force during the year 1918. One was reported in January and the other in April. I cannot say whether the latter went to Italy in the spring of 1918 nor whether the soldier was vaccinated.

#### *Treatment for Neurasthenic Patients.*

Major PRESCOTT asked the Pensions Minister whether he could make any statement as to the amelioration of the hospital arrangements for discharged sailors and soldiers suffering from neurosis and neurasthenia; whether he was aware that many of these Tottenham cases, together with those of epilepsy, were still awaiting admission into homes of recovery; whether he was aware that Mr. H. G. Cooke, a discharged soldier, of 39, Franklin-street, Tottenham, had been waiting for over five weeks to be admitted into

hospital; whether he was aware that a similar case which had been waiting for a similar period ended fatally a few days ago; and would he take immediate action to see that all outstanding cases were admitted to hospital without further delay.—Sir J. CRAIG (Parliamentary Secretary to the Ministry of Pensions) replied: This matter has engaged the serious attention of the medical officers. It is hoped that soon a central neurological institution will be established in each region, available for both in-patient and out-patient treatment. It is recognised that in a great number of neurosthenic cases in-patient treatment is not required, and in order to provide for this a number of clinics are being established in various parts of the country where expert out-patient treatment will be given. It is therefore confidently expected that very soon ample accommodation will be available for the efficient treatment of these cases. As regards the case of Mr. Cooke his admission to an institution has now been arranged. There was, unfortunately, a little delay in obtaining a vacancy in a suitable hospital. The other case quoted was complicated by the fact that the patient was also suffering from epilepsy, and it was from this disease that he died.

MONDAY, AUGUST 11TH.

#### Insurance Medical Benefit.

Mr. G. LOCKER-LAMPSON asked the Minister of Health if he could make any announcement about the proposed extension of medical benefit under the National Insurance (Health) Acts.—Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: The question of what changes, if any, in the existing medical benefit under the Insurance Acts will be proposed for 1920 is not yet decided. Various improvements in the conditions of service and the possible establishment of some of the additional matters that were suggested in the Estimates of 1914 have been under consideration at the Ministry and in conference with the practitioners, and will be further discussed with the new consultative councils, with the insurance committees, and with approved societies. But these matters are not yet in a sufficiently advanced state to admit of any precise statement from me to-day.

#### Seale-Hayne Hospital Victualling.

Mr. GEORGE LAMBERT asked the Secretary for War whether tenders had been invited for the Victualling of the Seale-Hayne Hospital, Devon; and when the promise made to evacuate this institution would be fulfilled.—Mr. CHURCHILL replied: Inquiry is being made as to the first part of my right honourable friend's question. As regard the latter part, I can add nothing at present to the letter that was sent to him on Friday last.

TUESDAY, AUGUST 12TH.

#### Medical Treatment at Ilford and Barking.

Sir PETER GRIGGS asked the Pensions Minister whether he was aware that notice had been given to stop the medical and surgical treatment of pensioners and discharged soldiers at the Ilford Emergency Hospital for the towns of Ilford, Barking, and district, some of these men badly requiring treatment, having had to leave their military hospitals too soon; and whether he would make arrangements for the doctors to be paid for continuing the work which they had done gratuitously in the past.—Sir J. CRAIG (Parliamentary Secretary to the Ministry of Pensions) replied: My right honourable friend is aware that the authorities of the Ilford Emergency Hospital have given notice to terminate the treatment at their hospital of pensioners and discharged soldiers at the end of next month owing to lack of accommodation. Arrangements will be made at the earliest possible date for providing the necessary and suitable treatment for discharged men in the areas mentioned.

## Medical Diary for the ensuing Week.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton:—

MONDAY, August 18th.—4.30 P.M., Lecture V.:—Gastric Ulcer. *Ætiology and Pathology.*

FRIDAY.—4.30 P.M., Lecture VI.:—Gastric Ulcer. *Symptoms, General and Special.*

A Course of Clinical Lectures for Advanced Students on Intermittent Blood Infections and their Relation to Certain Common Diseases of the Kidney, Prostate, Testicle, and other Organs will be delivered by Mr. F. Kidd:—

WEDNESDAY.—4.15 P.M., Lecture III.:—Hæmatogenous Infections of the Testicles and Bladder. *Clinical Course; Diagnosis; Treatment.*

## Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BARLING, SEYMOUR, C.M.G., M.S. Lond., F.R.C.S., has been appointed Honorary Surgeon to the General Hospital, Birmingham.

BERRY, W. A., M.D. (State Med.), B.S. Lond., D.P.H., Medical Officer of Health and School Medical Officer for the Heston and Isleworth Urban District Council.

COOK, W. W., M.R.C.S., L.R.C.P. Lond., one the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 2.

DAVIES, TREVOR B., M.D., B.S. Lond., M.R.C.P. Lond., F.R.C.S. Eng., Obstetric Surgeon to Out-Patients, Queen Charlotte's Hospital.

HARDY, T. LIONEL, M.B. Cantab., M.R.C.P. Lond., Assistant Physician to the General Hospital, Birmingham.

HOOD, J. H., M.B., Ch.B. Edin., Honorary Surgeon to the Royal Cornwall Infirmary, Truro.

QUINE, A. E., M.B., Ch.B. Vict. Manch., F.R.C.S. Eng., joint Venereal Diseases Medical Officer for the Cumberland and Carlisle City County Councils.

Certifying Surgeons under the Factory and Workshop Acts: LAVIN, M. F. (Ballymore Eustace District), FERGUSON, J. (Manchester, South-East District), REES-THOMAS, W. H., M.R.C.S., L.R.C.P. Lond. (Basingstoke).

## Vacancies.

For further information refer to the advertisement columns.

Adelaide University.—Prof. of Path. and Bact. £300.

Ashford, Kent, Grosvenor Sanatorium.—Sec. Asst. M.O. £250.

Barnsey, Beckett Hospital.—Res. H.S.

Bath City Council.—M.O.H. £700.

Battersea General Hospital, S.W.—Res. M.O. for Cancer Wing.

Birmingham Education Committee.—Asst. Sch. M.O. £300.

Bradford Royal Infirmary.—Res. Surg. O. £250.

Brighton Education Committee.—Sen. Sch. Doctor. £600.

Brighton and Hove Hospital for Women.—Hon. S.

Cairo, Egyptian Government School of Medicine.—Professors and

Lecturers. ££1,000 and ££600. Also Radiologist and Lect. in

Radiology, ££500. Anaesthetist and Lect. in Anaesthetics, ££500,

and Registrar and Tutor, ££600.

Canterbury, Kent and Canterbury Hospital.—Jun. Res. M.O. £150.

Carlisle, Cumberland Infirmary.—Res. M.O. £200.

Chester County Asylum.—Locum Tenens. 7s. per week.

Chorley Education Committee.—Asst. Sch. M.O. £400.

Derby, County Borough Education Committee.—Asst. Sch. M.O. £500.

Derbyshire Royal Infirmary.—Oph. H.S. £200.

Devonport, Royal Albert Hospital.—Res. H.S. £200.

Dunfriesshire Education Authority.—Med. Asst. £350.

Durham County Council.—Asst. Welfare M.O. £500. Also District

Tuberc. M.O.'s. £600.

East London Hospital for Children, Shadwell, E.—Cas. O. £120.

George Town Municipality, Penang, Straits Settlements.—Asst. M.O.H.

£4200.

Glamorgan County Asylum, Bridgend.—Fourth Asst. M.O. £400.

Great Yarmouth Hospital.—H.S. £200.

Greenwich Metropolitan Borough.—M.O. for Maternity and Child

Welfare Work. £540.

Guisborough Union.—M.O. £700.

Hong-Kong Government.—Bact. and Path. £600.

Hong-Kong University.—Lecturer in Biology. £400.

Huddersfield, Pontefract, and Wakefield, West Riding County Council.

—Dist. Tuberc. O.'s £500.

Ilford Urban District Council.—M.O.H. and Female Asst. M.O.H. £650

and £400.

Kent County Mental Hospital.—Jun. Asst. M.O. £300.

Khartoum, Wellcome Tropical Research Laboratories.—Asst. Bacterio-

logist. ££600.

King's Lynn, West Norfolk Hospital.—H.S. £150.

Leeds General Infirmary.—Ophth. and Aur. H.S. £50. Res. M.O. £60.

Two H.S.'s and Two H.P.'s.

Leeds Public Dispensary, North-street.—Res. M.O. £200.

Leyton U.D.C. Education Committee.—Asst. M.O. £350.

Liverpool, David Lewis Northern Hospital.—Three S.'s and Two P.'s.

£150.

Liverpool Hospital for Consumption, &c.—Vacancies on Hon. Med Staff.

Liverpool School of Tropical Medicine.—Tropical Research, Brazil.

£300.

Manchester, Ancoats Hospital.—Res. S.O. £200.

Manchester, Baguley Sanatorium for Tuberculosis.—Three M.O.'s.

£400, £350, and £300 respectively.

Manchester, Mosaic Fever Hospital.—First Med. Asst. £350. Second

Med. Asst. £300.

Manchester Royal Infirmary.—Med. and Surg. Registrars. £75.

Surg. Tutor. £30. Also H.S.'s. £25.

Manchester, St. Mary's Hospitals for Women and Children.—Res.

Obst. S. and Res. Surg. O. £250 each.

Melbourne University.—Lecturer in Pathology. £600.

National Hospital for Diseases of the Heart, Westminster-street, W.—

Res. and Non-Res. M.O.'s. £100 and £50.

Nelson, Lancs.—M.O.H. and Sch. M.O. £700.

Newark Hospital and Dispensary.—Res. H.S.

Newcastle-upon-Tyne, Hospital for Sick Children.—Sen. Res. M.O. £200.

Newcastle-upon-Tyne Poor-law Infirmary.—Second Res. M.O. (Female).

£250.

Newport Borough Asylum, Caerleon, Mon.—Asst. M.O. £300.

Northampton General Hospital.—Two H.S.'s. £200 each.  
 Northamptonshire C.C. Education Committee.—Sch. Dentist. £350.  
 Nottingham, Notts Education Committee.—Asst. School M.O. £425.  
 Prince of Wales's General Hospital, Tottenham.—Hon. Asst. P. and Hon. Asst. O. H.S. Also Clin. Asst.'s.  
 Putney Hospital, S.W.—Res. M.O. £150.  
 Queen's Hospital for Children, Hackney road, Bethnal Green, E.—H.S. and Cas. H.S. £100 each.  
 Rochester, Kent, St. Bartholomew's Hospital.—Jun. Res. M.O. £150.  
 Rochdale Infirmary and Dispensary.—Sen. H.S. £200. Also Jun. H.S. £100.  
 Royal National Orthopaedic Hospital, London, W.—Hon. P.  
 Royal Society, Burlington House, London.—Two Foulerton Studentships. £400 each.  
 St. George's Hospital, S.W.—Two Cas. Officers. £200.  
 St. Helen's Education Committee.—Whole-time Dentist. £450.  
 St. Mary's Hospital Medical School, Paddington, W.—Lecturer on Chemistry. £300.  
 Sheffield Royal Infirmary.—H.S. £150.  
 Shelland—Tingwell, Whithens, and Weisdale.—M.O. and Pub. Vac. £45.  
 Southampton, Free Eye Hospital.—H.S. £150.  
 Swansea General and Eye Hospital.—Res. M.O. £200.  
 Taunton and Somerset Hospital.—Res. Asst. H.S. £80.  
 Notice is given of a vacancy for a Specialist Medical Referee for Cases of Industrial Disease, in County Court Circuits Nos. 23, 28, 30, 31, and 54. Applications should be addressed to the Private Secretary, Home Office, not later than Sept. 4th.  
 Notice is given of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Sheriffdom of the Lothians and Peebles, and also for Circuit No. 11 (Bradford, Kelghley, Otley, and Skipton County Courts). Applications should be addressed, respectively, to the Private Secretary, Scottish Office and Home Office, Whitehall, London, S.W. 1, not later than Sept. 4th.  
 The post of Medical Adviser at Liverpool, under the Colonial Office, is vacant. Application for particulars should be made to the Colonial Office, London, S.W.  
 The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Abertillery, Bishop's Castle, Borrisoleigh, Darlington, Staveley, and Tallow.

## Births, Marriages, and Deaths.

### BIRTHS.

HILL.—On August 7th, at "Dalestead," Caterham Valley, Surrey, the wife of Fred. T. Hill, M.R.C.S., L.R.C.P., of a son (Anthony).  
 JEFFREYS.—On August 5th, at Brookvale-road, Southampton, the wife of Walter M. Jeffreys, M.B., of a daughter.  
 JOLY.—On August 10th, at Watford, the wife of James Moncrieff Joly, M.B., B.S. Lond., of Doo Doo Doo, Assam, of a son.  
 WHITNEY.—On August 7th, at High View, Maldon, Essex, the wife of C. Underwood Whitney, L.R.C.P., M.R.C.S. (late Captain, R.A.M.C.), of a son.

### DEATHS.

KNIGHT.—On August 7th, at his residence, Swansea, Frederick Knight, M.D. Lond., M.R.C.S., aged 59.  
 N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Communications, Letters, &c., to the Editor have been received from—

A.—Mr. P. A. Agutter, Wellingborough; Mr. R. J. Albery, Lond.; Sir R. Armstrong-Jones, Carnarvon; Mr. J. E. Arams, Lond.; Mrs. V. B. Alvarez, New York.  
 B.—Lieut. Col. Sir J. Barrett, Melbourne; Mr. J. B. Burke, Kingston Hill, British Dental Association, Lond., Sec. of; Dr. G. J. Branson, Birmingham; Mr. J. P. Buckley, Manchester; Mrs. C. Brereton, Lond.; Dr. W. A. Berry, Lond.; British Thomson-Houston Co., Lond.; Dr. E. A. Barton, Lond.; Surg. Commdr. W. Bastian, B.N.  
 C.—Dr. J. B. Crozier, Lond.; Dr. J. B. Christopherson, Lond.; Dr. F. G. Crookshank, Lond.; Dr. J. C. Clayton, Lond.; Colonial Office, Lond., Asst. Private Sec.; Dr. C. R. Corfield, Manchester.  
 D.—Dr. L. S. Dudgeon, Lond.; Sir D. Duckworth, Bt., Lond.  
 E.—Evelina Hospital, Lond., Sec. of.  
 F.—Food Education Society, Lond.; Dr. A. R. Fraser, Aberdeen; Factories, Chief Inspector of Lond.  
 G.—Major W. R. Galwey; Dr. A. L. Grant, Burghhead; Prof. G. Galli, Rome; Dr. H. L. Gordon, Lond.; Dr. R. G. Gordon, Bath; Mr. W. R. Gurden, Lond.  
 H.—Fleet-Surg. W. E. Home, R.N.; Dr. J. H. Hood, Truro; Dr. H.

Head, Chateau de la Mimerolle; Capt. H. A. Haig, R.A.M.C.  
 K.—Dr. H. C. Kidd, Bromsgrove; Dr. R. Knox, Lond.; Mrs. V. M. Kirkwood, Lond.  
 L.—Dr. C. E. Lakin, Lond.; Dr. W. J. Le Grand, Blackwell; Dr. G. C. Low, Lond.; Mr. E. M. Little, Lond.  
 M.—Manchester, School Medical Officer of; Dr. J. B. Mennell, Lond.; Mr. E. Miles, Lond.; Major P. Manson-Bahr, D.S.O., R.A.M.C.; Ministry of Health, Lond.  
 N.—National Association for the Prevention of Tuberculosis, Lond.; Dr. A. Napier, Glasgow.  
 P.—Mr. V. G. Piarr, Lond.; Mr. T. D. Pryce, Nottingham.  
 Q.—Queen Charlotte's Hospital, Lond., Sec. of.  
 S.—Dr. A. G. Shera, Eastbourne; Stoke Newington, Medical Officer of Health of; Dr. R. I. Spriggs, Banff; Mr. D. M. Shaw, Cheddar; Dr. E. B. Sherlock, Darenth; Student; Mr. S. Stephenson, Lond.  
 T.—Dr. A. H. Thompson, Lond.; Dr. J. Tatham, Oxted.  
 U.—University of Liverpool, Dean of Faculty of Medicine of.  
 W.—Dr. L. A. Weatherly, Bournemouth; Dr. F. J. Wethered, Falmouth; Mr. H. Wiltshire, Lond.  
 Y.—Mr. P. Yates, Manchester.

Communications relating to editorial business should be addressed exclusively to the Editor of THE LANCET, 423, Strand, London, W.C. 2.

## Notes, Short Comments, and Answers to Correspondents.

### AN EMERGENCY CASES HOSPITAL IN THE MEUSE.

BY J. A. CAIRNS FORSYTH, M.Sc., M.B., F.R.C.S.,

SURGEON TO THE FRENCH HOSPITAL.

(Concluded from p. 272.)

#### The Defence of Verdun.

On Feb. 23rd, 1916, wounded began to arrive from Verdun. They were in a bad way, and very "jumpy," having suffered much during the terrible bombardment, which they described as something quite extraordinary in the way of shell fire. Certainly some of the shells which fell around Verdun were of uncommon size.

The first fortnight of that historic battle will always live in our memories. Work was at the highest pressure on account of the constant stream of wounded that flowed through Bar-le-Duc. How the staff of the Evacuating Hospital stood the strain I do not know, but they went about their work uncomplaining, their bodies limp with fatigue and their eyes heavy from want of sleep.

The battle was practically directed from Bar-le-Duc, which soon became a very busy place. You will all have read of the wonderful motor transport service that was so quickly organised to assist the railway transport, for the only railway to Verdun that was of any service was a narrow gauge line, and much time was lost in transferring material from broad gauge wagons to narrow gauge. 24,000 motor lorries made the tour to Verdun and back, each day and night. Bar-le-Duc was so policed that no civilian vehicles of any kind were allowed in, and even military vehicles had to enter by one way and leave by another. Stopping or turning in the main streets was prohibited. On the roads to Verdun traffic was as well managed, and each class of troop and transport had its different route, according to the speed of its travelling.

With the opening of the battle there hurried to the Verdun front numerous British ambulance sections belonging to the British Ambulance Committee, the British Red Cross, and the British Committee of the French Red Cross. All of them got arduous and dangerous work transporting wounded from the "postes de secours."

#### Shell Wounds and Gas Gangrene.

The wounds received around Verdun were in quite another class from those of the Argonne fighting in 1915. They were practically all shell wounds, horrible tearing smashes, and the proportion of fractures was very high. Of the 3000 wounded that came to us in 1916 over 1000 had compound fractures, many of them multiple. Gas gangrene was also very rife, and we had 266 cases of gross gas infection, gas that could be detected by the senses. Of these 266 cases 179 were of the local type, and the majority remained so. Only eight of these patients died. The remaining 87 were cases of the fulminating type, where a whole limb or a large area such as the shoulder, back, or buttock was involved. 59 of the 87 died. Included in this series are eight cases of that curious condition, "white gangrene" of the lower limb. The limb then had the appearance of a gigantic phlegmasia alba dolens, and the toxæmia was especially profound. In seven of the eight cases the whole limb was affected and all died. The remaining case was atypical, for the condition extended up only to the knee. That case got well.

#### French Colonials.

As the battle continued we were brought more and more into touch with the Colonial troops of France—Arabs from North Africa, blacks from Senegal, Somaliland, and the French Soudan, Annamites from French Indo-China. In the French hospitals there was no separation of the coloured men from the white—they were treated just like the others, except that in the case of the Arabs and certain blacks their food had to be in accordance with their religious laws. Many of the blacks partook of anything that was going, but the Arabs were most particular in their diet.

Of all these men of colour we were specially attached to the primitive black. They were a most well-behaved, polite lot of men, who showed an almost dog-like devotion to those who ministered to their wants. Some of them were men of huge stature, yet they were among the gentlest patients that ever entered the hospital. One gathered from their officers that they were terrible fellows in the fight, giving no quarter and asking for none. At times they were difficult to hold, especially under heavy shell fire, but once launched at the attack they proved their mettle. Then they were prone to

throw away their rifles, and they entered battle armed only with this fearsome knife, "coup coup" as they called it, that deals a blow akin to that of the Gurkha kukri. One can imagine the effect on the Bosche when he saw a regiment of these ebony giants coming on, brandishing such weapons.

#### *The Nightly Alerte:*

In the autumn of 1917 there commenced a long period of bombing of the Meuse district, no doubt in response to the bombing of German territory by the British Independent Air Force. It was an anxious time, especially during the month of September, when we got the "alerte" every night. Bar-le-Duc suffered badly, one corner of it being blown away. The Credit Lyonnais was burned to the ground, and the civil hospital had to be evacuated. Revigny suffered in like manner, especially round the railway station and the artillery park. We soon realised, however, after the first few nights that the Bosche did not intend to harm our hospital. When they had finished bombing Revigny they crossed the ridge and made for our lake as a rallying point. Keeping well down so as to be safe from the guns, which could not fire low on account of the ridge, they passed over us at a height of about 100 yards. With our wards plainly visible in the moonlight, our unit must have been an excellent target, but they left us alone.

#### *British Wounded from Champagne.*

In the spring of 1918 the great German offensive commenced, and among the wounded who came to us from the Champagne were many British. They had been badly knocked about, and we were glad to see them. A few weeks later and the wounded Highlanders of the 51st Division arrived, but now things had got the turn and the Bosche was being pushed back. These were the days of open warfare and bullet wounds, and it was quite a pleasure to treat bullet wounds after the shell wounds of Verdun, for few of them suppurated.

Summer saw the advent of the American Army to Verdun and the Argonne, and the gradual replacement of the French by their troops. We now had to rely entirely on the army of the Champagne for patients, and many came to us from that army of Colonial regiments. Our hospital had quite a "café au lait" appearance, and our only regret was that we did not speak Arabic.

#### *A Long Farewell.*

With the signing of the Armistice, we got leave to return to England, so we packed up our tents and stole away. Our last patients went into the interior or "en permission," vowing undying friendship, and the hospital was then rapidly dismantled. The bulk of our equipment was sent to a château near Paris, recently purchased by the British Committee of the Croix Rouge, and presented to the French as a sanatorium for consumptives.

We said good-bye to our many friends in the district, and took a sad and long farewell of Faux Miroir. It had been our home for over three years and we were loth to leave it, but we came away with the pardonable feeling that we had been of some assistance to a nation in the hour of her sorest need. Verdun now is but "a tale that is told" in comparison with the more recent glories of the Western front, but to us there will ever remain the memory of that great defence and the sacrifice it entailed. The part that our unit played may have been small and unimportant, but perhaps it may be that the equal treatment of all the specimens of humanity of the French world, the fair division of kindly gifts and comforts from home, the little sprees and sing-songs, have done something towards that real kinship of nations—kinship in human suffering.

#### THE ILL-EFFECTS OF THE AMOURS OF OLD MEN.

At a recent meeting of the Académie de Médecine of Paris M. Armaingaud, the author of a remarkable book entitled "L'Homme vers la Fin de sa Vie," discussed an important subject which seems to have escaped systematic treatment—the ill-effects of the amours of old men. Individual observations on the point must have been made from time to time in general practice, but their interpretation, being doubtful, they have not been thought worth recording, though they have given rise to a general impression. Having practised for 35 years in a very large French town and enjoyed both the confidence and the friendship of an important clientèle, M. Armaingaud has had special opportunities for investigating the subject. In many families the old men preserved all their faculties and remained vigorous until an advanced age. But there were others who fell into idleness and suffered from ennui. They were rich business men aged 50 to 65 years or more, who had retired after making their fortunes. Though in good health and intelligent, their moral and their physical strength declined sensibly in one or two years and their characters changed. Their wives often took M. Armaingaud into their confidence, and

said that the old man, formerly charming and benevolent, loving his grandchildren much and taking them on his knee, became indifferent. He often became depressed, bad-tempered, and exacting. If not told it, M. Armaingaud quickly divined that he had a mistress of 20 to 35 years. From the earliest period of his career his observations tended to convince him that genital excesses were often the cause of apoplexy, cerebral congestion and softening, heart affections, and rapid decline of intelligence and power in men of 60 to 70 years. He resolved to study the question as soon as he had the cases which would enable him to do so. When such a case arrived his view was confirmed. He told the anxious wife to send her husband to him as soon as he complained of the slightest malaise. Questioning led the patient to admit that he had a mistress, generally young. M. Armaingaud pointed out the ill-results, reminding him of the death of a contemporary, which was due not to age but to excess, absolute or relative, and after 60 or 65 years very little indulgence might constitute excess. He added that it was to old men especially that the saying applied, "*Post coitum omne animal triste*." In 38 cases 12 patients would not give up the mistress, 7 did so for a few years and then relapsed, 19 did so permanently. The 12 who did not were from 62 to 66 years of age (average 63). They died at an average age of 73 years. They lost on the average four years of life, for the expectancy of life, according to the tables of French insurance companies, for 63 years is 14 years. The 7 who partially followed the advice were aged 60 to 69 years (average 65). According to the tables, their average expectancy was 13 years, bringing the average age at death to 78. But 6 died at an average age of 75; 1 was an exception and lived till 80. The 19 who did take the advice were aged from 63 to 69 years (average 66). Three, who were exceptions, lived until 68, 70, and 72 years; but the 16 others, who had an average expectancy of life of 12 years—that is, to 78 years—lived until an average age of 86 years, 13 years more than the first class and 11 than the second. The Arab proverb quoted by Professor Lacassagne in his book, "The worst things for an old man are a good cook and young woman," expresses a great truth.

#### "DIADEM" TALCUM POWDER.

It is well known that talc provides an excellent dry lubricant for toilet purposes. Its curious greasy or soapy feel is a remarkable characteristic. In "Diadem" powder a particularly fine impalpable talc is selected as a basis, agreeably perfumed with unirritating agents. In addition there is present a well-known antiseptic powder also in a finely divided state. Altogether this toilet powder reaches a very good standard, having regard to the purposes for which such preparations are employed. The specimen was submitted by Messrs. Robartes, Ltd., Dyer's Buildings, Holborn Bars, London, E.C.

#### MOTHERCRAFT.<sup>1</sup>

THIS useful little text-book is somewhat incorrectly described as a "new edition," for, apart from the many new chapters, some of those under the old titles are by new authors, and many of the original chapters are omitted. Among the most useful of the new chapters is one by Dr. J. S. Fairbairn on "Pregnancy as Affected by Maternal Disease," in which he describes and discusses the common diseases which are associated with pregnancy, and those caused by the pregnancy itself—chiefly the toxæmias of pregnancy.

Dr. Eardley Holland contributes a particularly useful chapter on "Venereal Disease in Relation to Dead Birth and Infant Mortality." An account is given of the nature and course of syphilis, its effect on the fetus, its mode of transmission, and the methods of treatment. He points out the importance of syphilis as a cause of antenatal mortality, and urges the necessity for the examination of every macerated fetus by an expert for evidence of this disease.

One of the most important and useful additions is the chapter by Dr. Henry Kenwood on "Child Welfare and Cow's Milk: Our Duty." So far the public demand for clean milk has met with little or no response, but we can only hope with Dr. Kenwood that this will not always be so. He condemns in no uncertain language the milk which is at present sold, and which is so frequently used as a food for infants. He says that "much of the milk which is sold is dangerously dirty, and this dirt in milk is responsible for much infant sickness and mortality, especially in the summer months. From 5 to 10 per cent. of all the samples of cow's milk examined have contained the cow germ of consumption, and in young children nearly half the fatal cases of abdominal tuberculosis are due to this germ. Occasionally milk infected

<sup>1</sup> Mothercraft. A Selection from Courses of Lectures on Infant Care delivered under the auspices of the National Association for the Prevention of Infant Mortality. Third edition, revised and enlarged. London: John Bale, Sons, and Danielsson, Ltd. 1919. Pp. 320. 5s. net.

by human agencies causes epidemics of diphtheria, enteric fever, scarlet fever, &c.; 10 per cent. of all the samples of milk taken under the Sale of Food and Drugs Acts in England and Wales and submitted to the public analyst are found to be adulterated." Simple tests which can be applied by any intelligent person are given for the content of cream, and the presence of dirt or sourness. It is impossible to mention in detail the subjects which are dealt with so helpfully, but those which will be found of great use include Causes, Recognition and Prevention of Dental Defects, by Mr. C. Peyton Baly; Diseases of the Skin in Infancy, by Dr. H. G. Adamson; and the Law Relating to Maternity and Child Welfare, by Dr. T. Shadick Higgins. In the appendix is given a selection of the best answers to questions on infant care which have been set by the National Association for the Prevention of Infant Mortality at the examination held at the conclusion of each course of lectures. The answers are reproduced as a guide to other students, and will, with the examiner's note, be of great assistance to health visitors and others who intend to present themselves as candidates at future examinations.

#### A MEDICAL REFORMER.

IN its "News, Notes, and Queries," the *Liverpool Post* appositely remarks that Parliament would be much the better these days if it could boast a Joseph Hume, who set himself to check Ministerial extravagance and abuses wherever he could detect them, and maintained a small staff, at his own expense, for ferreting out and exposing everything prejudicial to the public purse. So formidable did he prove that Ministers framed their estimates in fear of him. Joseph Hume was born on Jan. 22nd, 1777, and was the son of a Montrose shipmaster. On the death of his father, his mother was forced to sell crockery in the market-place, but managed to send her son to school, and in 1790 he was apprenticed to a local surgeon. Subsequently, he studied medicine at Aberdeen, Edinburgh, and London, and entered as a surgeon in the sea service of the East India Company. He was afterwards transferred to the land service of the Company, and having mastered Hindustani and Persian was employed in political duties. In 1801 he joined the army at Bundelcund as a surgeon, and during the Mahratta war rendered the Government important services, including a means of drying the stock gunpowder which had become wet. Leaving the army, having somehow amassed £40,000, he spent some time in travel and study, publishing in 1812 a translation in blank verse of the *Inferno* of Dante. His political career at home began in the same year, and he was represented at different times Weymouth, the Border burghs, Aberdeen, Middlesex, Kilkenny, and Montrose. Like his personal and political friend, the Founder of THE LANCET, the late Thomas Wakley, he urged the abolition of flogging in the army. He was a Privy Councillor, a Fellow of the Royal Society, and twice Lord Rector of Aberdeen University. He died in 1855.

#### PREGNANCY AND CHILD BIRTH AMONG SIBERIAN ABORIGINES.

Miss M. A. Czaplicka, a Russian lady who lived for some years in Siberia among the primitive people, has shed a good deal of light on the mode of life, habits, customs, and superstitious practices in a book entitled "Aboriginal Siberia, a Study in Social Anthropology" (Clarendon Press, 14s. net). Among other things she has collected data relating to pregnancy and childbirth, some of the more interesting of which are here given with the names of the tribes concerned:—

*The Kamchadal*.—According to Krashenninnikoff, an eighteenth-century traveller, a woman gave birth to a child kneeling and in the presence of all the villagers without regard to sex or age. The newly born child was wiped with and wrapped in a species of grass called *touchitch*; a stone knife was used to cut the umbilical cord, and the placenta was thrown to the dogs. A woman who wished to become pregnant had to eat spiders; some women for this purpose would eat the umbilical cord together with a grass called *kiperi*. On the other hand, if a child was not desired there was a widespread custom of causing abortion by shock, or by killing *in utero*. The old women "specialists" who carried out the operation frequently caused the death of the mother. In order to induce sterility concoctions made from certain grasses were taken.

*The Yukaghir*.—All cases of childbirth among the Yukaghir were very difficult, and the barbarous practices attendant on them produced nervous diseases and premature age in the mothers. The foundation of these practices is the belief that difficult labour and unfortunate birth are caused by the entry of an evil spirit into the woman. Difficult labour is also attributed either to the failure of the mother to observe certain taboos or to the ill-will of the child itself. Therefore two pregnant women are not allowed to live in the same house in case the two unborn children should communicate and decide which mother should die. Sometimes the husband helps his wife who is in difficult labour by placing his arm around her abdomen. The taboos connected with childbirth affect not only the mother, but also the rest of the household. Some of these taboos are: the pregnant woman must not eat the fat of the cow or reindeer, or larch-wood, as these things are believed to "freeze" or thicken in the stomach and to fasten the child to the inside of the uterus; but butter of the cow or horse's fat may be eaten. She ought not only to be active and

energetic during the puerperium, but ought, in walking, to raise her feet high and also to kick away stones or lumps of earth in her path, thus symbolising the removal of obstructions at childbirth. At the first attack of labour-pains not only the wife, but the husband and midwife, must loosen all their garments, so that the child may not be hampered in any way.

*The Chukchee*.—This tribe is one of the most prolific in North-East Asia, and the women are delivered with little trouble. Custom forbids the mother receiving any help at childbirth—help may only be given in cases of absolute necessity. She must not groan, and has to attend to her own needs as well as to those of the new-born infant. She cuts the cord (with a stone skin-scrapers) and pulls away the placenta. Accordingly, a large pelvis—because it eases delivery—is considered one of the chief features of womanly beauty.

*The Gilyak*.—The Gilyak woman never dares to give birth to a child at home; she must, in spite of the severity of the weather, go out of the hut for this purpose. In late fall or winter a special hut is built for the woman, but it is a very uncomfortable affair, so that mother and child suffer from exposure to cold and wind. To help the woman in labour a wooden figure is carved, representing a woman in the act of delivery, and to it are sacrificed different kinds of foods, with a view to placate the evil influences which are at work. Special knives are used to cut the cord. The woman returns home on the eighth or ninth day. A woman who wishes to have a child wears various amulets, such as a dog's tooth, &c.

*The Buryat*.—Among the Buryat of Alarsk during delivery the women of the family are gathered near the mother and take the child and drop it in a horizontal position on the floor, which has been made soft for the purpose, after which it is washed and wrapped up. Two or three days later a feast is held at which the ceremony of wrapping up the child begins. A boy or girl present is chosen to reply to questions put by a temporary "mother," who holds in her hands an arrow and a right haunch of bone of an animal. After the questions have been asked and answered three times a name is given to the child. The feast ends with the making of a fire in the place where the birth occurred; the guests, including the father, surround the fire and squirt into it from their mouths a mixture made from meal and oil, all in one voice exclaiming "Give more happiness! Give a son!"—repeated three times. General excitement prevails and they vie with each other in smearing their friends' faces and clothes with oil, ashes, and fresh animal excrement.

*The Yakut*.—Yakut marriages are generally fruitful, averaging ten children to one woman, but becoming less so towards the northern districts, although the Yakut are everywhere more prolific than the Tungus. The lack of children is ascribed solely to the woman. According to the explorer Jochelson, women from the north have very difficult delivery. The Yakut regard the pangs of childbirth as sickness caused by evil spirits, and therefore if the assistance of a midwife or the goddess of fertility, Aylsit, is of no avail, a shaman is called in to fight the spirit. A Yakut woman is always delivered on the bare earth, for the Yakut believe that the "earth-soul" is communicated to the infant from the earth at the moment of birth. No consideration is shown to mother or child, for women possessed of evil spirits are regarded as no less perilous to society than those infected with epidemic disease. This accounts for the cruelty manifested by the Yakut towards women suffering the pains of labour. Cases have been known where the woman has died as a result of such cruelty. To hasten delivery two posts are driven into the ground and a third one is fastened across the top of them. The woman kneels and places her arms over the cross-piece far enough to bring the latter under the arm-pits. One man from behind holds her shoulders and another in front holds her hands to prevent any possibility of her resisting the operations of the midwife. The latter kneels in front of the patient and presses upon her abdomen, at the same time imploring the aid of the benevolent goddess, Aylsit, who is believed to be present at childbirth and to assist the patient. Certain food taboos are observed before childbirth: the expectant mother must eat neither swan's flesh nor wild birds' eggs, because the child might otherwise be deaf and imbecile.

The customs collected by Miss Czaplicka are found among aborigines more or less all over the world. The custom mentioned as existing among the Yukaghir of the spectators loosening their garments is in one form or other very old. It was a belief of ancient Roman and Greek folklore that the goddess of delivery, Lucina or Ilithyia, could hinder delivery according to the attitude which she took up, a belief referred to by Herrick, who says, "At thy birth Lucina cross-legged sat."

#### REDUCING A DISLOCATION.

Retired Major, R.A.M.C., asks:—"What are the chances of successfully reducing a backward dislocation of both bones of the forearm in a boy of 12 years, five weeks after its occurrence? What is the latest time after which such an injury has been reduced?"

## Methods of Treatment

OF

## FRACTURES OF THE FEMUR.

BY JAMES DRIBERG, M.C., F.R.C.S.,

LATE CAPTAIN, R.A.M.C.; SURGICAL REGISTRAR, LONDON HOSPITAL.

IN no branch of surgery has the present war done more to modify treatment than in that of fractures of the femur, and not only to modify but also to simplify the treatment. Whereas in pre-war days a different splint was regarded as more or less specific for each variety of fracture, the present method is to treat all forms of fracture of the femur, and even of the whole leg, in a Thomas knee-splint.

By this means every sort of deformity can be entirely overcome and an ideal result obtained, whereas it is to be remembered that in the pre-war days shortening of from one to two inches was common with a simple fracture, and the results of compound fractures often hopeless.

It is true that in many cases of war wounds with gross destruction of bone and tissue the ideal has been impossible to attain; but these war wounds are, we hope, things of the past, and the object of this paper is to apply the methods learnt and studied in the war to civil practice, in which, happily, compound fractured femurs are rare, and seldom do we see the ghastly shattering of a limb as may be caused by a high-explosive shell.

It is not difficult to see why the treatment of fractured femurs should have improved to so great an extent. In civil hospitals before the war there would seldom be more than 15 to 20 fractures in the same hospital at the same time, and these under the care of various surgeons and house surgeons, all working independently. Whereas during the last two or three years it has been possible to go to any military fractured femur centre and see anywhere up to 500 cases, all under the care of the same surgeon (with, of course, adequate assistants). The treatment of these large numbers of fractured femurs has been systematised—team work has been introduced, and it has been possible to compare results on a scale which has never before been practicable. The natural outcome of this is that the treatment of fractured femurs has been vastly improved.

The treatment of fractured femurs falls automatically into two main groups: (1) the surgical; and (2) the mechanical. They are both important, but it must not be forgotten that the surgical is the life-saving treatment, and therefore must always take precedence, when necessary, of the mechanical.

## I. SURGICAL TREATMENT.

This naturally confines itself to compound fractures—and whereas in war-time the greater percentage of fractured femurs were compound, in civil practice the reverse holds good. In war wounds energetic surgical treatment had to be adopted—the wounds widely excised, damaged tissue excised, muscle cut away till healthy, bleeding, contractile fibres are reached, all fragments of metal and clothing extracted—because of the great dangers of infection partly by ordinary pyogenic organisms and partly by specific gas-forming bacilli, which were so disastrous to life and limb before adequate surgical treatment was adopted. The wound should not be stitched, but should be packed with gauze soaked in flavine, brilliant green, or some form of antiseptic; this dressing should not be changed, and the wound should be closed by delayed primary suture on the third day, with a rubber drain inserted at the lower end for 24–48 hours.

In civil practice if there is any suspicion of gross infection, such as in badly lacerated railway or other accidents, these same surgical measures should undoubtedly be carried out, and so eliminate the sepsis that used to be so common and disastrous. If there is extreme shock this has to be treated by the usual methods—the application of heat and the injection of morphia, or strychnine, or of some other stimulant. There is also no doubt that in cases of shock, especially if associated with hæmorrhage, blood transfusion is of great value. When the patient is fit for operation the depressing effects of chloroform and ether may be obviated by administering gas and oxygen anæsthetic.

In most cases it will be found that these compound wounds heal well, and with little trouble. But if sepsis supervenes

dependent drainage is essential. If drainage is not satisfactory the pus tracks up the thigh towards the hip-joint, especially along the adductor and ham-string muscles, and along the sheath of the sciatic nerve. The temperature chart taken on a "septic" character, the pulse-rate rises, the tongue is dry and dirty, an intractable diarrhoea may set in, there is risk of secondary hæmorrhage, and if adequate drainage is not supplied both limb and life are in danger.

*Secondary hæmorrhage.*—Secondary hæmorrhage, which used to be the bugbear of military surgeons, is now, fortunately, becoming more uncommon. It is treated by tying the bleeding point; if this is not possible the main artery may have to be ligated, but this only too often ends in gangrene and subsequent loss of the limb. If a severe hæmorrhage has taken place intravenous transfusion of normal saline gum solution or blood may be necessary.

*Tetanus.*—Another condition in compound fractured femur which may require surgical treatment is tetanus. In every case where dirt has entered the wound it is advisable to give a prophylactic dose of antitetanic serum of 1500 units, followed eight days later by a smaller dose. If tetanus supervenes any drastic treatment, such as amputation, is contra-indicated. Various sedatives have been used, but experience has shown that the best is morphia—in  $\frac{1}{4}$  gr. doses, given four-hourly, or as often as is necessary to control the spasms. Large doses of antitetanic serum (10,000–12,000 units a day) should be given intramuscularly. Intrathecal injections have not been found to give better results, and have been more or less universally discarded. The severe spasms of the thigh muscles in the "local" form of tetanus may interfere with the extension and position of the bone fragments, but they are usually amenable to treatment. In one case, under Major E. C. Lindsay, R.A.M.C., and operated on by Colonel Percy Sargent, D.S.O., the spasm of the adductors was so severe and uncontrollable that eventually the obturator nerve had to be exposed and crushed, with a satisfactory result.

## II. MECHANICAL TREATMENT.

This consists of (a) fixation of the limb; (b) extension of the limb; (c) suspension of the limb.

Before proceeding to the consideration of these three it is necessary to say a few words about the bed. Any hospital or other bed with an iron framework will suffice, and it is not necessary to have a special mattress with a movable segment for dressings; for, by the method presently to be described, it is easy for the patient to raise his body well clear of the bed for dressings, bed-pan, and other nursing necessities.

Attached to the bed is a wooden framework for the purpose of extension and suspension of the limb, and this should be as simple as possible; there should be two upright bars at the foot of the bed, one at each corner, reaching about 5 feet above the level of the bedclothes. These are joined by a cross-bar at the top and a cross-bar about 2 feet lower down; this lower cross-bar can be extended outwards on either side if the fracture is in the upper one-third and abduction is required. At the head end of the bed are two similar upright bars, but these are clamped on in the centre of the bed about 4 inches apart. From the top of each of these is a longitudinal bar running to the upper cross-bar at the foot of the bed, placed in position for either leg with the requisite amount of abduction. Each of these longitudinal bars has four pulleys on it, one at the foot end, one in the middle about the level of the patient's pelvis, and two at the head end.

Having dealt with the bed and the framework, and having got the patient into bed, it is now possible to consider the fractured limb.

## (A) FIXATION.

By fixation is meant the application of a splint to the fractured leg and the retention of the leg to, or in, that splint. Many splints have been used, the best known being Liston's, Macintyre's, Hodgen's, and the Thomas knee-splint. Gradually every form of splint has been discarded by the majority of surgeons in favour of the Thomas knee-splint or one of its modifications, and this is the only splint whose method of application need be described. There may be a few forms of fracture, especially of the upper one-third, which are more easily treated in a Hodgen's splint; but there is no type of fractured femur which cannot be treated adequately in a Thomas knee-splint.

Before the splint is actually applied the leg has to be prepared in some way so that it may be fixed in the splint. To do this a general anæsthetic should be given, unless

contra-indicated by the general condition of the patient or some concomitant disease, such as Bright's, diabetes, &c. All manipulation of the leg is painful, and an anæsthetic helps both the patient and the surgeon. The various methods of fixing the leg are:—

#### 1. Methods which Obtain Traction from the Skin Surface.

(a) *Adhesive strapping.*—This is probably the best in all cases where traction is applied directly to the skin surface. The method of application is so well known that it is unnecessary to describe it, except to say that it need not be applied above the knee. The skin of the leg need not be shaved beforehand. The purpose of shaving was to make removal of the strapping more comfortable, but by the time the strapping is ready to come off the hairs will all have grown again. And, in any case, strapping can be painlessly removed with ether or turpentine.

(b) *Glue.*—This was first introduced by Major M. Sinclair, C.M.G., of the R.A.M.C. It consists of commercial glue made up according to the following formula: glue, 50 parts; water, 50 parts; glycerine, 2 parts; calcium chloride, 1 part; thymol, 1 part.

Two strips of gauze, 8-fold thick and 5 inches wide, are cut long enough to reach from the knee to 6 inches below the bottom of the Thomas splint. The leg is then washed with a solution of sodium bicarbonate (3i. ad Oi.) in order to remove all grease from the skin. The glue, heated to melting point, is then applied to the skin of the leg between the ankle and the knee as evenly as possible. It is preferable to apply this with the hand and not with a brush, for with the hand it can be applied more evenly; and also this method ensures that the glue is not too hot for the patient's skin. The two strips of gauze are then placed evenly on the glue, one on either side of the leg, and about as high up as the tuberosity of the tibia. The whole leg from just above the ankle to just below the knee is bandaged firmly, but evenly, with a 3-inch cotton bandage. It is essential that the bandage and gauze should be evenly applied, for any unevenness is bound to cause blistering of the skin. If, after the glue has dried, the bandage is too tight, it can be snipped with a pair of scissors. A common place for blistering is over the tendo Achillis, and here, if necessary, the bandage can be cut for an inch or two without harm.

The glue takes about ten minutes to dry, and the chief advantage is the ease and speed with which it is applied. Its disadvantages are that it has to be renewed more frequently than strapping and is rather apt to blister the skin, causing pain and discomfort to the patient.

(c) *Mastisol.*—This is a rubber solution which is applied in exactly the same manner as glue. It dries more rapidly, but is rather more apt to blister the skin.

#### 2. Methods which Obtain Traction Directly from the Bone.

(a) *Fixation by calipers.*—This is the ideal method, as it gives direct control of the lower fragment of bone, and in careful hands no sepsis or ill-results ensue. The calipers are shaped like ordinary ice-tongs, the ends being pointed, and, when opened at the angle at which they will be applied, in the same straight line with each other. The first calipers to be used were ordinary commercial carpenter's calipers, the ends being curved and bent in. Since then various types have been devised, the latest and best being that of Major M. G. Pearson, S.A.M.C., which has in the handles a screw adjustment which prevents any further penetration of the bone once the calipers are fixed in position.

There are two methods of applying the calipers. In the first slight penetration of the bone is aimed at, and this method is adopted if fixed extension is afterwards going to be applied, for otherwise any movement on the part of the patient which eases the extension momentarily might cause the calipers to slip. In the second method the calipers are introduced down to, but not penetrating, the bone. With weight and pulley extensions there is a constant pull at all times, so there is no tendency for the calipers to slip. The points of the calipers get a perfect grip on the bone, which is maintained by the pull of the weight; the screw adjustment in the handles of the calipers prevent penetration of the bone, and the extension cord attached to the handles prevents the points of the calipers coming apart.

The technique of applying the calipers is simple, but all due antiseptic and aseptic precautions must be taken.

The skin round the knee having been shaved and prepared for operation, and the patient having been given a general anæsthetic (gas and oxygen is usually quite sufficient), an incision is made with a scalpel down to the bone on each

side immediately above the thickest and most prominent portion of the condyles of the femur. Each incision should be half an inch long. If the incision is too short pressure sepsis may result in the skin and cause considerable pain. The sterilised calipers are then taken and the points inserted down to the bone, one in each incision. If penetration of the bone is desired the points are hammered in with a mallet to a distance of from  $\frac{1}{2}$  to  $\frac{3}{4}$  in., and the screw in the handle of the calipers adjusted till the handles just touch each other. In no case is it necessary to drill a hole in the bone beforehand. If penetration of the bone is not desired the same steps are carried out, except that the points of the calipers are not hammered in. The handles of the calipers are then tied together to prevent separation of the points. A piece of cord about 3 ft. long is then tied to each handle. To keep the incisions over the condyles clean it is merely necessary to apply to each a piece of gauze soaked in iodine or flavine or some other antiseptic; this piece of gauze need never be removed, but every two or three days a few drops of the antiseptic should be poured on to it.

Calipers are contra-indicated in fractures of the lower one-third actually involving the knee-joint if there is distension of the synovial membrane, because of the danger of damage to the membrane; also in lower one-third compound fractures with T-shaped fracture into the knee-joint, for then the pressure of the calipers may cause pocketing and accumulation of pus between the fragments.

General diseases, such as diabetes, &c., are no contra-indication, for the calipers may be applied under gas and oxygen or local anæsthetic. The same is true of a septic wound over the condyles, for the introduction of calipers actually into a septic wound neither increases the sepsis nor inhibits healing, provided the calipers are only applied down to the bone and there is no penetration.

Occasionally, in spite of careful technique, a slight, though painful, skin sepsis may arise, or the calipers may slip owing to an orderly or nurse relieving the extension by lifting the attached weight (a thing which they should strictly be warned not to do); in these cases the calipers should be removed and reinserted at a somewhat higher level.

The patient usually suffers a little pain and discomfort for 24 hours, sufficient to warrant the injection of morphia gr.  $\frac{1}{2}$  before the anæsthetic.

The two risks of calipers are bone sepsis and penetration of the knee-joint; with careful technique neither of these ought ever to occur.

(b) *Ankle calipers.*—They are similar to, though smaller than, the femur calipers. They are applied in exactly the same way, and with the same precautions, into the thickest part of the malleoli. They are useful in those cases where, owing to the involvement of the knee-joint, &c., femur calipers are contra-indicated; and especially so if there should also be a fracture of the tibia or fibula.

(c) *Hey Groves's transfixation pin* is a steel rod which is driven through the lower end of the femur just above the thickest part of the condyles—traction being maintained from either end of the rod. This has to pass through the cancellous and easily infected portion of the bone, and in removing the pin one end—which has been exposed, has possibly become septic and is difficult to re-sterilise—has to be pulled through the bone, and infection may result.

(d) *Tibial screws.*—These are two silver screws, 2 in. long, which are screwed  $1\frac{1}{2}$  in. into the tibia about 6 in. below the knee-joint. A cord or tape is attached to each screw so as to maintain traction. They have no particular advantage, but may be useful if the skin of the leg blisters badly with strapping or glue.

(e) *Schutro's stirrup.*—This consists of a short, narrow steel rod, which is inserted between the tendo-Achillis and the bone, and rests against the os calcis. Traction is maintained from each end of the rod. This method, too, has no marked advantage over others; and in unskilled hands the steel rod has been known to cut through the tendo-Achillis—a most unfortunate accident.

#### Strapping and Calipers.

The next consideration is which of these eight methods to apply. Except in special cases it is probable that only one of two methods will be adopted; these two are strapping and calipers. There is no doubt that the best results are obtained with calipers. Having a direct control on the lower fragment ensures more accurate correction of any displacement. With this method the period of convalescence is decreased; for, as massage and passive move-

ments of the joints can be applied from the very beginning, the patient, when union has taken place, is able to walk with a good, strong, muscular, well-nourished leg. Moreover the increased nutrition, due to massage, &c., very probably has a beneficial effect on, and hastens, union; for it is a fact that patients who have calipers applied do get union somewhat sooner than those who have some other form of fixation.

There are certain cases, which have already been discussed, where calipers are contra-indicated. In these cases strapping should be used. Also, where aseptic and anti-septic conditions cannot be guaranteed the caliper method, perhaps, should be discarded; for any sepsis round the caliper points, though not necessarily of surgical import, causes great pain and necessitates the removal of the calipers. And, finally, the personal equation of the medical attendant and the facilities at hand for operative treatment have to be taken into consideration.

#### *Application of the Splint.*

The leg having been prepared in one of these methods for fixation, the next step is the application of the splint. Some surgeons prefer a Thomas splint with a large ring, but most use one with a small ring, on the grounds that it is more comfortable for the patient and allows less lateral movement at the seat of fracture.

Having chosen a well-fitting Thomas knee-splint, it is passed on to the leg. An assistant should throughout apply traction on the leg from the ankle, in order to limit as far as possible movement of the bone fragments and consequent damage to the tissue of the thigh. The leg is then supported in the splint by slings. These are short lengths of 3-inch flannel bandage. Each one is looped over the inner bar of the Thomas splint, the doubled bandage is then passed under the thigh and fixed in position over the outer bar by safety-pins or by 3-inch paper clips, which are much more convenient and easy to use. The sling under the upper end of the lower fragment should be pulled tight and should always be kept tight, for this sling corrects the backward displacement of the lower fragment. By having this sling tight the lower fragment is pulled forward into position with the upper, and the anterior arch of the femur is restored. Malunion of the femur with backward displacement of the lower fragment is the most disabling form of malunion known. The other slings merely form a trough for the leg, and are slackened or tightened according to the comfort of the patient.

The ring of the splint should fit snugly against the tuber ischii, the cord from the strapping or the calipers or the gauze from the "glue method" is tied firmly to the end of the splint, and the leg is now "fixed" in the splint.

If strapping has been used it is advisable to bend the Thomas splint to an angle of about  $15^\circ$  at the level of the knee-joint. This, of course, is done before the Thomas splint is put on to the leg. By doing this the knee is slightly bent and the gastrocnemii muscles are relaxed, so helping to correct the backward displacement of the lower fragment.

If calipers have been applied a straight splint should be used and a "knee-flexion splint" applied.

The "knee-flexion splint," introduced by Major M. G. Pearson, consists of the lower part of an ordinary Thomas knee-splint cut off to a length of  $2\frac{1}{2}$  ft. At each upper free end is a joint and a thumb-screw. The knee-flexion splint is fixed to the under surface of the Thomas knee-splint by the thumb-screws, which should be opposite the knee-joint. The flannel slings below the knee are now transferred from the Thomas to the knee-flexion splint, and the leg below the knee is allowed to hang in the knee-flexion splint. This it will do by its own weight, for it must be remembered that when calipers are applied the whole of the leg below the knee is free. By means of the joint between the upper end of the knee-flexion splint and the thumb-screw the splint can be moved up and down, and so passive movement given to the knee-joint daily throughout the whole time that the patient is under treatment. This is the greatest advantage of the caliper method, for it obviates any stiffness of the knee-joint, which is so common with other forms of fixation and which is nearly as crippling as malposition of the femur. The lower end of the knee-flexion splint is tied to the lower end of the Thomas splint by a hook and chain, and can be adjusted to any angle.

To prevent "foot-drop" a small, rectangular wire foot-piece is strapped on either to the Thomas or the knee-flexion splint, and the foot fastened to this in correct position. The most convenient way is to take a strip of gauze, fix one end to the sole of the foot with glue, and tie the other end to the

top of the foot-piece. This leaves the dorsum of the foot free for massage, and also allows of a certain amount of passive movement of the ankle-joint.

#### (B) EXTENSION.

There are two main methods of extension—fixed extension and "weight-and-pulley" extension. It must be remembered that fixing the leg in the splint does not provide extension. It may appear to do so temporarily, but if no further measures are adopted the leg very soon lies quite loose in the splint, partly due to stretching of the gauze or the cord, and partly due to relaxation of the muscles of the thigh.

If fixed extension is to be used the bottom end of the Thomas splint is tied firmly to the lower of the two wooden cross-bars at the foot of the bed, and the foot of the bed is raised 12 inches on blocks. The patient is only allowed one pillow under his head. This method of extension is very simple.

The leg is fixed in the splint, the splint is fixed to the foot of the bed, which is raised on blocks, and the body weight continually slipping away forms a counter-extension and pulls the leg out. If several pillows are allowed the patient puts them under his shoulder, and this immediately releases the extension. In most cases of recently fractured femurs, the leg can be pulled out to its correct length in 24 hours or even less. When this result has been obtained, and that can only be determined by careful measurements and by the X ray, the patient can be allowed an extra pillow, but this may have to be taken away again if the leg shortens at all; it is most important to keep up full extension for the first three to four weeks. The patient may complain of discomfort for the first day or two—it is usually due to the unaccustomed position—but he very soon gets used to it and becomes happy and comfortable. It is unusual for there to be any pain in the seat of fracture once extension has been applied. There may be pain in the thigh due to trauma received at the time of injury, but this is usually relieved by small doses of aspirin.

If "weight and pulley" extension is employed, the lower end of the splint is again tied to the cross-bar at the foot of the bed; but the cord from the strapping or calipers, instead of being tied to the bottom of the splint, is attached to a weight and passes over a pulley which is screwed into the cross-bar opposite the lower end of the splint. The foot of the bed is not raised on blocks. A weight of 7-10 lb. is usually quite sufficient, and it is seldom necessary to use more than 15 lb. In fractures several weeks' old with some union in malposition it may be necessary to have a heavier weight. It must be remembered that when the calipers do not penetrate the bone they are kept in position chiefly by the pull of the extension weight. Consequently, anyone in charge of the patient, such as nurses, orderlies, &c., must be carefully warned never to lift the weight; for this immediately relaxes the extension and the calipers are then liable to slip. In order to ensure against this accident occurring it may be as well to have a small wire cage fitted to the foot end of the bed, inside which the weight may hang. The cage will not only remind the staff that the weight is not to be disturbed, but it will also prevent the weight from being knocked by passers by.

The advantage of the "weight and pulley" method is that the foot of the bed need not be raised and the patient can be propped up as much as is desired by pillows, bed-rest, &c., which in elderly or bronchitic patients greatly reduces the danger of hypostatic pneumonia. With the "weight and pulley" extension the patient sometimes complains of pressure pain over the tuber ischii, and occasionally a definite sore appears. With fixed extension this never happens, for the body weight pulls the upper end of the thigh out of the ring of the Thomas splint.

But apart from these there is nothing to choose between the two methods. Equally good results are obtained with both, and after the first day or two the patients are equally comfortable in either position.

The other methods of extension are not so satisfactory, and need only be shortly described.

*Spring extension.*—The cord of the strapping or calipers is tied either to a powerful elastic or a strong steel spring, which in turn is fixed to the lower end of the splint. With this the amount of extension is difficult to gauge and regulate.

*Screw extension.*—As in the Wallace-Maybury splint.

The patient's leg is fastened to a wooden foot-piece, which is pulled away by an adjustable screw. This is not a very comfortable method for the patient, nor is it very accurate, though it is sometimes useful for purposes of transport.

## (C) SUSPENSION.

The object of suspending the limb is three-fold: (1) it enables the patient to move about comfortably in bed; (2) the necessary rotation of the lower fragment may be obtained so as to correspond with any outward rotation of the upper fragment; (3) in the "weight-and-pulley" method of extension the ring of the splint can be kept close up against the tuber ischii and prevented from slipping over that bone, thus ensuring satisfactory counter-extension from the tuber ischii.

In order to suspend the leg four lengths of cord and four weights of about 5 lb. each are necessary.

The cords are attached to the splint, two at the foot and two at the upper end just below the ring—one on the inner and one on the outer side. They are then passed through the pulleys which have been fixed to the two longitudinal bars of the wooden framework, and finally the weights are attached to the free ends of the cord and hang down behind the patient's head. The two cords from the foot end pass through the two pulleys at the foot end of the bed and then through two of the four pulleys at the head end. The two cords from the upper end of the splint pass first through the two pulleys midway along the longitudinal wooden bars and then through the remaining two pulleys at the head end.

In order to get outward rotation of the leg and lower fragment it is merely necessary for the weights attached to the two inner suspension cords to be slightly heavier than those attached to the two outer suspension cords.

With this suspension method the patient can lift himself off the bed with the greatest ease. He should, of course, have a rope with a wooden handle above his head by which he pulls himself up, at the same time assisting by bending up his sound leg and levering himself off the bed with his heel. The whole weight of the fractured leg is taken by the four suspension weights and the patient has practically only the weight of his trunk to support. Most patients can easily raise themselves 12–18 inches off the bed, and remain in that position long enough for purpose of dressing, nursing, &c.

If the patient is very weak and debilitated another method can be used for keeping him raised up.

A strong piece of flannel, 2 ft. long by 10 in. wide, is passed under the patient's back. Each end of the flannel is looped and through each loop is passed a narrow bar of iron (the bar of a Thomas splint, cut down, answers the purpose very well); each bar is fixed from its centre to the longitudinal wooden bars of the framework by a hook and chain. The flannel binder can be adjusted to any height and the patient remains raised comfortably for as long as is necessary.

Five pounds is the average weight necessary for each suspension cord, but this varies, and can be adjusted to the size and weight of the patient; and, as already mentioned, outward rotation of the leg may be obtained by increasing the weight attached to the inner two cords.

To recapitulate, the steps in "putting up" a fractured femur are: 1. The wooden framework is clamped on to the bed. 2. Some method of traction is applied to the leg. And of all the methods it is probable that only one of two will be adopted—either strapping or calipers. 3. The splint is put on; the slings applied and the leg firmly fixed in the splint; knee-flexion splint adjusted if it is used. 4. Extension (fixed or "weight and pulley") is applied. 5. The leg is suspended. This is the procedure in every case of fractured femur. Variations in the treatment of individual cases will be considered later on.

So far nothing has been said about fixing the bone fragments by direct control at the seat of fracture—i.e., by plating, wiring, or screwing. The plating of fractures is a large subject and quite beyond the scope of this article. Moreover, one of the objects of this article is to show that perfect results may be obtained by other methods. Plating, in the hands of experts, may give excellent results, but in inexperienced hands may have most disastrous consequences. Furthermore, plating does not diminish the length of time the patient has to remain in bed, nor does it shorten the period of convalescence. It is merely a method of internal, as opposed to external, splinting. And as equally good results may be obtained by other methods, it seems unnecessary to expose the patient to the risk of a lengthy anæsthetic and a severe operation. There is a small percentage of cases in which plating may be necessary; these will be considered later on amongst the complications of fractured femur. In no case of compound fracture should plating be even suggested.

## VARIETIES OF FRACTURE.

The next step to consider is the varieties of fractured femur, the position of the fracture, and the bony displacements. The varieties of fracture—transverse, oblique, spiral, comminuted, &c.—have been so often and ably described in text-books that they need not be discussed here, especially as they each require identically the same treatment. Their only importance is with regard to the length of time extension should be maintained, and they will be considered later on under that heading.

Of much greater importance is the situation of the fracture. Of late it seems to be the fashion to divide the femur into fourths, but this has absolutely no advantage over the previous system of division into thirds.

1. *Fracture of the Upper Third.*

(a) *Intra-capsular fractures of the neck of the femur* show little displacement, and merely require fixation, slight extension, and extreme abduction until union is complete.

(b) *In extra-capsular fractures of the neck* shortening is the main displacement to be overcome; this requires considerable extension and usually slight abduction. The result has to be accurately checked by X ray and the tape measure.

(c) *Fracture of the upper one-third of the shaft.*—The usual situation is just below the small trochanter, and the displacement is typical and very general. The displacement of the upper fragment is three-fold—flexion, abduction, and external rotation. Flexion is caused by the upward pull of the iliopsoas muscle; abduction is caused by the glutei; and outward rotation by the external rotators of the hip—obturator, pyriformis, quadratus, and gemelli. Consequently the lower fragment has to be similarly displaced in order to bring it in line with the upper. External rotation is obtained by increasing the weights attached to the two inner suspension cords; abduction, by prolonging outwards as far as necessary the lower cross-bar to which the lower end of the Thomas splint is fixed, and flexion is already provided for by raising the lower end of the splint up to the level of the lower cross-bar.

It has been stated that in order to get true abduction both legs should be abducted, otherwise the patient twists himself round in bed, tilts his pelvis, and false abduction occurs. This is not correct. For the abduction that is applied in order to bring the fragments into line takes place at the seat of fracture and not at the hip-joint, and there is no inducement for the patient to tilt his pelvis; for this position, which restores the natural alignment of the leg, is the position of greatest comfort and rest. That this is so can be proved by examining the anterior superior iliac spines of a patient with one leg abducted; it will be found that the spines are at the same level. In this the treatment of upper-third fractures varies from that of tubercular disease of the hip-joint, in which double abduction is necessary. An exception to this is also found in intra-capsular fractures of the neck of the femur, where extreme abduction is desired, and it is advisable widely to abduct both legs. In upper-third fractures the lower fragment is pulled up by the hamstrings and inwards by the adductors; this is corrected by extension. In fractures above the small trochanter the only difference in displacement is that the upper fragment is not pulled forward by the iliopsoas.

2. *Fractures of the Middle Third.*

The upper fragment is very slightly abducted and externally rotated; the lower fragment is displaced upwards and inwards. This displacement is usually easy to correct; the shortening is reduced by extension, and any "sagging" or backward displacement by tightening the supporting slings. It is essential to keep these slings firm in order to restore the anterior curve of the femur.

3. *Fractures of the Lower Third.*

In these the lower fragment is always pulled back by the gastrocnemii, and usually adducted and slightly rotated outwards by the adductor magnus. The lower fragment is also pulled up by action of all the thigh muscles.

Shortening is corrected by extension; and the backward displacement by tightening the sling under the lower fragment, and by flexing the knee, which relaxes the gastrocnemii muscles. Flexion of the knee is easily obtained by using the knee-flexion splint, already described. The use of calipers is more essential in this than in any other type of fracture, for often it is the only possible method of controlling

the short and easily displaced lower fragment, and of allowing the full amount of knee flexion that is so essential.

In all fractures backward displacement is more or less easy to correct by tightening the supporting slings. Lateral displacement can be similarly corrected. If, for example, the lower fragment is displaced inwards and is not corrected by extension, a flannel sling is passed round the thigh at the level of the upper end of the lower fragment and pinned securely to the outer side bar of the splint. This will pull the lower fragment out, and the sling can be further tightened daily until good position is obtained and maintained.

Of the various fractures those of the upper third usually require more extension than those of the middle or lower. That shortening and displacement have been correctly reduced is decided by inspection, palpation, measurement, and radiography. Inspection and palpation will show whether the limb looks normal as regards size and shape, and whether the anterior and outward curve of the femur has been correctly restored, but the only true and satisfactory tests are measurement and radiography.

Transverse fractures of the femur are rather more difficult to get into perfect position than the other varieties, but once in position their natural tendency is to keep in that position. Oblique, spiral, and comminuted fractures are very liable to "telescope" if good extension is not kept up.

In all varieties of fracture, except the transverse, it is desirable to apply sufficient extension to obtain 1 cm. lengthening; the reason for this is that as soon as the patient starts to walk there is a tendency for the callus to contract and the limb to shorten up just a trifle. This is more particularly marked in cases where there has been a prolonged sepsis and the callus is "sticky."

Both legs should be measured daily for the first week or ten days in order to be certain that sufficient extension is being applied; after that it is only necessary to measure the legs every few days. Sometimes, especially in compound comminuted fractures with much laceration of the thigh muscles, there is over-correction with lengthening of the limb. In this case the amount of extension is reduced, in one method by decreasing the amount of the weight attached, and in the other by allowing the patient more pillows or by putting the foot end of the bed on lower blocks. The legs should be measured in centimetres, which decreases the margin of error, and can be carried out either with a tape measure from the tip of the anterior superior iliac spine to the internal malleolus or with a wooden measure from the under-surface of the anterior superior spine to the upper border of the patella.

It is convenient to chart the length of the leg each time. It is measured on a special chart drawn out in centimetres. The normal line is the length of the sound leg, and the amount of shortening or lengthening is charted above and below this line respectively.

#### *Radiography Essential.*

Radiography is absolutely essential if good results are to be obtained.

The patient is photographed in bed with a portable X ray apparatus. Either two views, antero-posterior and lateral, are taken, or the leg is photographed stereoscopically from the anterior view. If the position of the bone is not satisfactory an attempt is made to correct the deformity by the methods described and a further radiograph taken. Once the position and length are satisfactory it is only necessary to radiograph the leg every two or three weeks in order to be certain that the correct position is being maintained. It is convenient and useful, though not always possible, to have small reduced prints of these radiographs pasted on a board and hung by the patient's bedside.

During the entire time that the patient is in the splint massage of the whole limb and (if calipers have been used) passive movements of the joints should be carried out; it is also advisable to have massage of the sound leg, so that when the patient starts to walk all his muscles are strong, and he is able to stand up and retain his balance. Passive movement of the knee-joint of the broken leg is obtained by daily alteration in the level, and movement of the knee-flexion splint; this should at first be done very carefully and for the first two or three weeks, at any rate, by the medical attendant himself, for in the early stages any careless movement might cause some alteration in the position of the fracture, and will certainly cause pain.

#### *Length of Time during which the Leg should be Left in the Splint.*

This varies to a certain extent, but, on an average, the splint can usually be dispensed with at the end of the tenth or eleventh week. Fractures of the lower third, probably because of the excellent blood-supply, seem to unite rather quicker than those of the upper and middle thirds. Oblique, spiral, and comminuted fractures should be kept in the splint, with extension, for a week or ten days longer than transverse fractures. For in transverse fractures, provided the position of the fragments is good, the interlocking of the two ends prevents any shortening, bowing, or sagging.

The only real method of judging whether the leg is fit to come out of the splint is by palpation and the X ray. By firm palpation it is possible to estimate whether the union is firm, and whether there is any mobility at the seat of fracture. Any tenderness, on pressure, in the fracture, means that the callus is not yet firm enough. X rays at this stage are very important. They demonstrate the amount and density of the callus. The presence of callus first appears in a radiograph about the end of the fourth week as a very faint haze; this gradually increases in extent and intensity, till about the tenth or eleventh week it appears as a dense homogeneous mass, firmly knitting all the bone fragments together. In compound fractures, if there has been marked sepsis, the callus may present a honeycombed appearance. Such callus is weak and points to the need of further treatment in the splint.

Having decided, about the tenth week, that the leg may soon come out of the splint, the extension can be removed and the leg left merely fixed in the splint and suspended. In the "weight-and-pulley" method, the weight is removed and the cord tied to the end of the splint, which is loosened from the cross-bar. In the fixed extension method the bed is taken off the blocks, the patient is allowed as many pillows as he desires, and the splint loosened from the cross-bar; it will be found that the patient has slipped out of the splint for an inch or two, and it is necessary to readjust the splint so that the ring fits snugly against the tuber ischii; the cord is then fastened firmly to the lower end of the splint.

This may be called the second position and it is continued for a week or ten days. During this period the patient is encouraged to move about as much as possible in bed, in order to exercise thoroughly all his muscles preparatory to walking. It is possible and desirable for the patient to get out of bed and sit in a chair by the bedside, his broken leg being suspended the whole time.

During this period, too, massage is actively continued. And, by suspending the leg higher in the bed, the knee-flexion splint can be further dropped till the knee bends to an angle of 90°. If strapping has been used instead of calipers the leg can be taken out of the splint daily under supervision of the medical attendant and knee movements started.

About the eleventh week the leg is taken out of the splint permanently. The patient should be able to lift the leg clear of the bed, if his muscles have been kept in good tone by massage, &c., and there should also be appreciable active movement of the knee-joint. He is kept like this for a further three or four days, the leg being supported on a pillow. The leg must be carefully watched lest any bowing or sagging takes place, in which case the splint must be reapplied at once, for it means that union is not sufficiently firm.

Union being firm enough and the patient being used to freedom from the splint, he is now allowed to walk; but for at least another three months he is not allowed to put any weight on the heel, for the callus is not firm enough to take the body weight. This difficulty is overcome by the use of what are called "walking calipers" or "caliper boots." These consist of a Thomas knee-splint with the lower end cut off and the loose points turned in and fitted into a hole drilled through the heel of the boot.

#### *Measurements.*

The measurements required by the splint-maker are:—

- (1) The circumference of the thigh at the level of the tuber ischii; (2) the length from the tuber ischii to  $\frac{1}{2}$  in. below the sole of the foot.

The splint-maker chooses a splint with a neatly padded well-fitting ring, cuts the lower end of the splint off and fits the two loose ends with a sliding screw adjustment 6 in. long. With this the length of the splint can be varied, so as to be accurately adjusted to the leg. Each of the screw

pieces has a transverse steel rod attached to the lower end  $1\frac{1}{2}$  in. long, which fits into a hole in the heel of the boot. The outer bar of the splint should fix into the heel of the boot 1 inch in front of the inner bar, so that when the bars are level the boot is turned out and corresponds to the natural eversion of the foot in walking. If this is not done considerable discomfort will be caused.

When the splint is on the leg and fixed into the patient's boot the heel should not touch the bottom of the boot. If it does touch the splint should be lengthened by a few turns of the screw adjustment. If the heel touches the boot the weight of the body is transmitted through the fracture and may cause bending. If the heel does not touch all the weight is taken by the tuber ischii. In a correctly fitting splint very little weight should be taken by the great trochanter or the pubic bone.

Provided both legs are of the same length, the good leg should be raised by a 1-inch patten on the boot; this is to enable the bad leg to swing clear of the ground in walking, for, of course, while in the walking splint it is impossible for the knee to bend.

At first the patient will have to be assisted and supported in walking, but usually he very soon can walk alone. It is purely a matter of self-confidence and balance; even if he were to fall down he would not fracture his leg while it was in the walking splint. Crutches are not necessary and are to be discouraged; one, or sometimes two, walking sticks may be used, but the patient quickly learns to walk without any form of support at all.

Every morning before putting on the walking splint massage and passive movement should be given; and two or three times during the day the splint should be freed from the boot and knee movements actively exercised.

The caliper boots should be worn until at least six months have elapsed since the date of fracture; by that time the splint can be discarded and the patient walk naturally and with a perfectly movable knee-joint. Here, again, an X ray is of great value. If the callus is very dense and bone canaliculi can be discovered, then the callus has been converted into true bone and can only be broken by trauma, such as would be needed to fracture any sound, healthy femur.

On first getting up the patient may find that his leg swells considerably. This will gradually disappear as his muscular and vaso-motor systems regain their normal tone. As the muscles of the thigh grow bigger it may be necessary to have a fresh splint with a larger ring.

#### SOME COMPLICATIONS OF FRACTURED FEMURS WHICH MAY OCCUR.

(1) *Mal-union*.—In early cases—that is, in simple fracture up to about six or seven weeks and in compound fractures up to the end of the twelfth week—it is usually possible to break down the union by hand and apply satisfactory extension. In later cases osteotomy will be required if the deformity and disability are sufficient to warrant it.

(2) *Delayed union and non-union* may be caused by (a) sepsis with formation of a large sequestrum; after sequestrectomy with satisfactory drainage the bone usually unites rapidly; (b) gross destruction of bone, so that when extension is applied the ends of the bone are too far apart for union to take place. This may be treated either by bone-grafting or by deciding to allow some shortening and relaxing the extension, so as to permit of the ends of the bone coming together. When union is taking place, but while the callus is still "sticky," increased extension will probably cause a little more lengthening without interfering with union.

Delayed union may be caused by general disease, such as debility, malnutrition, anemia, cachexia from malignant disease, tabes dorsalis, rickets in childhood, &c. The treatment of the disease is the treatment of the delayed union; but assistance may be given by some form of passive congestion of the limb, such as Bier's treatment.

In spite of treatment a few cases of fractured femur will not unite; occasionally this may be due to pieces of muscle fascia or other tissue which have been caught between the bone ends; but usually the reason is obscure. No fractured femur should be diagnosed as a case of non-union till at least 12 months from the date of injury; and then if there is still no union, surgical treatment may be considered. It is doubtful if plating will ever help if the ends of the bone are already in good position; in these cases it is probably better to adopt some form of bone-grafting. Even when the bone has been plated the freshening of the bone ends during operation, and the increased supply of blood brought to the parts during

the healing of the operation wounds probably play as big a part as the plate itself in stimulating the bone to callus formation.

(3) *Tetanus* has already been discussed.

(4) *Nerve lesions* form a subject for treatment beyond the scope of this article. It is sufficient here to say that if "foot-drop" is present an uplifting toe-spring can be easily attached to the walking caliper splint.

(5) *Neuralgic pain along the dorsum of the foot* is not very uncommon. Its cause is obscure. It cannot be entirely due to a neuritis of the sciatic nerve as it is met with both in simple and compound fractures. It may be treated (often without marked success) by drugs such as aspirin, bromide, phenacetin, &c., or by local applications—heat; cold; ointments, such as ung. methyl salicylate, 2 per cent.; formalin solution; blisters; antiplogistine, &c. Sometimes a rubber bandage firmly applied gives relief. Unfortunately the pain is always worse at night and is often sufficiently severe to keep the patient awake. The pain, though not very amenable to treatment, usually decreases and disappears after a few weeks.

(6) *Stiffness of the knee* due to adhesions in the thigh between muscle, fascia, and bone. This is, of course, much more common in compound fracture, especially where there has been marked sepsis. The worst cases, and most difficult to treat, are when the extensors of the thigh are bound down to the bone by scar tissue. The scar may be loosened by massage and forcible flexion under an anæsthetic. Sometimes the scar can be separated from the bone by the introduction of a tenotome. If these methods fail excision of the scar will be necessary.

#### CONCLUSION.

In conclusion it may be said that by the methods that have been described a perfect result can be obtained in the vast majority of fractured femurs. But, like everything else, a fractured femur requires constant care and attention to detail. The adjustment of the slings, the maintenance of extension, the movements of the knee-joint, the correct suspension with slight eversion of the limb, the prevention of foot-drop, massage, and the upkeep of general health and nutrition of the patient—each of these plays its allotted part in the attainment of perfection; and if anyone is neglected the seeker after perfection is apt to be disappointed.

### PERVERTED "FUNCTIONAL" ACTIVITY IN THE PRODUCTION OF JAW DEFORMITIES.

BY D. M. SHAW,

CURATOR OF THE PROSTHETIC LABORATORIES, ROYAL DENTAL HOSPITAL OF LONDON.

THE "perverted" or non-normal activities which it is desired here to draw attention to are "functional" only in so far as they are excited and exhibited in the oral preparation of alimentary substances. The "jaw deformities" that it is hoped to throw some additional light upon are those occurring among children, and chiefly recognised and estimated (in occlusion) as irregularities or abnormalities in the position of teeth, the teeth themselves emerging structurally sound and normal in shape. The various dental units are constructed faultlessly and are ready (we may assume) to time. They are then potentially available for building into a machine which is highly efficient as a food-preparing mechanism when the units are normally arranged, and which then also, when normally exercised, is adapted to maintain the health and integrity of its various parts and investing tissues. But in the abnormalities frequently seen the functional efficiency is greatly depreciated; the specific shapes that in man have for ages remained morphologically constant are there present, but the teeth are thrown together in such disorder as to more or less abort their utility, and the normal *rhythmical* activity in mastication becomes impossible. It will be agreed, and without touching at all upon the many other consequences involved, that this is a somewhat poor beginning for that part of the alimentary processes over which we could safely exercise the most direct and most knowledgeable control:

*The "Soft Food" Theory.*

Any references to current theories of causation will here be closely restricted to what may seem helpful in bringing my proposition into reasonably clear view. Absence or insufficiency of the harder foodstuffs has long been held to be a dominant cause of malocclusion. The "soft food" theory and the indicated remedy have been insistently kept in the forefront by several accepted authorities, and in the general lay and professional mind there is, at any rate, a pious if not a very active belief in the soundness of that view. While no one seeks to deny that by lack of functional exercise the jaws may fail to attain their full development, there are yet large groups of malocclusion cases (involving protrusions, retrusions, contracted arches, spread arches, and excessive anterior overlap) wherein this explanation has been rejected by the majority of those interested in the subject. The limb muscles of different children undergo widely differing amounts of exercise; in many individuals the exercise may be deficient in amount, but no concomitant bone deformity ensues.

Professor A. Keith, whose suggestion that the "sensitising" action of the pituitary secretion may be at fault was so finely lit up by the searching beam he cast into the less-explored field of comparative odontology, is at the same time in entire agreement that one should also give exhaustive attention to those "grosser" agencies which are known to alter and regulate growth—"the mechanical impulses which arise from the natural use of parts."

Quite a number of alternative explanations have been offered with varying degrees of confidence and support. The difficulty and low solubility of the problem being illustrated by the emergence, for example, of theories of causation, some of which are diametrically opposed—viz., the theory held by Dr. Sim Wallace and Sir Arbuthnot Lane that contracted or narrow jaws are caused by a feeble musculature of the tongue resulting mostly from the use of *soft food*, and the explanation advanced by Professor H. P. Pickerill that narrow jaws are due to the use of food that is too *hard or tough*. Again, in regard to defects or wrong use of the respiratory ports as a factor in jaw deformities, although the vitiating physical or mechanical conditions that exist during *free mouth breathing* are distinctly different to the conditions during *obstructed nasal breathing*, and therefore the effects directly due to the former must differ markedly from those due to the latter cause, yet in articles and discussions those important differences are usually either glossed over or ignored.

*The Existence of Positive Factors.*

Whether or no in modern times a harmful change has taken place in the kind of food given to children, the number of meals per day has probably not lessened and the total time given to eating may be taken as not less now than was customary among children in the near or more distant past. Therefore, as the mouth is in *some* kind of activity during that time, inquiry into the effects or defects arising should not be confined to consideration of the merely passive or negative factors. The absence of positive factors cannot be assumed, and they should be searched for and their value as far as possible ascertained by close and persistent observation of the *machine at work* in large numbers of children. For some years past I have missed no opportunity (and have artfully created a good many) of observing the different ways in which the mouths of children deal with food.

A direct view of what is going on in the mouth is, of course, very much cut off and masked by the cheeks and lips, but this drawback is in some degree compensated for by the fact that watchful observation of those same moving curtains will often betray what is happening behind the scenes. Correct interpretation of the mouth and jaw movements which take place and of the probable results of the various efforts in manipulating food will, it is reasonable to believe, be favoured a good deal by previous close study of the chewing mechanism in children and adults, and not only in normal but also in abnormal, crippled, and mutilated dentitions. The small amount of interest up to the present taken in the physiological morphology does not warrant however, the entering into details, "tedious" details that are in reality essential in this as in any other mechanism. The following is a rough summary of the results of observation of many groups of children.

1. There is in many cases an excessive amount of manipulation of food *by the tongue*. The tongue movements vary from very languid to very energetic, sweetened foods usually exciting the tongue to the greater activity, especially in upward pressure.

2. The normal work of fine reduction *by the cheek teeth* is only partially carried out, and is often not performed at all. Morsels are merely rolled about in the mouth, with an occasional squeeze from tongue or teeth, and what are in reality remarkable feats of food-bolting pass quite unnoticed. The performances of some of these juvenile, yet often well-mannered, "bolters" are so mysterious and *finished* that it is almost impossible to understand how it is done.

3. Certain foodstuffs which constitute a large proportion of the daily intake (including cereals and breadstuffs permeable and softened by saliva, sweetened puddings, &c., porridge, sweets, jam, and confectionary) are manipulated and "mashed" by the tongue *against the anterior surface of the palate*, partly to break up their consistency and partly to develop and extend the gustatory enjoyment. Sucking actions are often involved, and among the several reflex actions excited by very sweet substances is a frequent strong pressure of the anterior dorsal surface of the tongue against the front of the palate. In these various movements the muscular pressure exerted by the tongue is *many times greater* than that required either for the successive liftings of portions of food into position between the cheek teeth or for moving food from one part of the mouth to the other. Here we have a kind of "tongue mastication" (*vide* Mr. J. G. Turner) which, while admittedly falling within the limits of normal function when performed occasionally, becomes *abnormal* or perverted when exercised frequently and to the extent of in large part supplanting normal mastication by the cheek teeth.

4. In some children—more usually of the "vigorous mouth and hearty eater" type—the reduction of *tough morsels* is to an abnormal extent effected *by the anterior teeth* instead of by the cheek teeth, which latter teeth may either be absent or crippled by caries, or, if present, they are thrown out of effective shearing alignment by a malocclusion already established. In this type the cutting edges of the anterior teeth are found to be more worn—and to an undue or abnormal extent—than those of the posterior teeth. Later on one may often observe premolars and molars that have been fully erupted for several years and yet show not a trace of intermaxillary attrition or of food abrasion. Now, when for any reason fine (or moderately fine) reduction of tough food is attempted by the incisors alone, the tongue has to exert considerable upward and forward pressure in order to *hold the small morsels in proper position* for each successive shearing stroke (Fig. 1.) This work of reduction (which by the arithmetical increase of the divided fragments must constitute by far the greater part of the total masticating effort) is effected normally by the multi-bladed cheek teeth, in which the rows of lingual cusps automatically, as it were, hold and support the fragments in position, and without calling for more than the very lightest use or pressure of the tongue.<sup>1</sup>

*Some Predominant Features in Malocclusion.*

The bearing of the above-mentioned perverted activities of the tongue upon jaw deformities may here be best brought out by a short consideration of certain features that are often found associated in various classes of malocclusion.

FIG. 1.—Strong forward pressure of the tongue is always exerted when *small* tough morsels are reduced by the incisors, and is required in order to hold the morsels in proper position for shearing. Externally the small morsel is held by the lips, as indicated at L. This action may become abnormal in frequency when the cheek teeth are lost, or crippled by caries, &c. It always involves an upward and backward pull upon the inner surface of the mandible, as at P.

<sup>1</sup> "Mechanism of Mastication in Man." Trans. Sixth Internat. Dental Congress, p. 63 et seq. "Form and Function of Teeth," Journ. Anat. vol. lili., October, 1917.

Twenty years ago (1899) the adjourned discussion of a paper on "The Treatment of Superior Protrusion," read by Mr. J. F. Colyer at the Odontological Society of Great Britain, included a full and interesting contribution from Mr. E. Lloyd-Williams on the aetiology of that deformity. In the discussion following—deservedly a "classic" upon the particular subject—all the known explanations were in turn advanced, excepting perhaps only the ductless gland theory and the antenatal and parturition theories. Yet, as one of the speakers very moderately expressed it, "there was still something missing in all the hints which had been thrown out with regard to causation."

There was general agreement upon the points mentioned by Mr. W. Hern and Mr. Lloyd-Williams as to the

FIG. 2.—High level of incisors, without "crowding" of crowns.

following three or four abnormalities found associated in the majority of superior protrusion cases: (1) The high level attained by the alveolar anterior border of the mandible; (2) shortening of the body of the mandible; (3) the increased depth or low level of the premolar and molar region in both maxilla and mandible; (4) some narrowing of the arches; (5) a backward "bite" of all, or nearly all, the mandibular teeth. (Figs. 2, 3, and 4.)

#### *Significance of the Abnormal Vertical Overlap.*

The high level or uprising of the incisive border of the mandible involves, ipso facto (excepting only in cases of "open bite") an abnormal degree of vertical overlap in the occlusal relationship of the incisors, the opposed incisors quite often overlapping one another to the full length of their crowns—that is, from two to three times more than the normal amount. Now it is a remarkable and perhaps hardly recognised fact that if and when—from whatever cause—this excessive overlap is in any particular case once established, the several other abnormalities set out above must then of mechanical necessity be concomitant, if not

FIG. 4.—The excessive anterior overlap, seen from behind.

actually consequent, features. This statement requires qualifying in regard to the fourth abnormal feature, inasmuch as the arch in some cases does not undergo a general narrowing. But excessive overlap must in most cases involve a narrowing of, at any rate, the anterior portion of the mandibular arch, because the lower anterior teeth are shifted to a smaller "circle" (shorter tract) within or behind the lingual walls of the upper ones; the only two alternatives possible being a broadening (anteriorly) of the upper arch, or an excessive retrusion of the lower one. Excessive overlap is a feature of many cases other than those of superior protrusion, and the search for its origin—as probably the master-key to the causal explanation of many jaw deformities—has always made a fascinating appeal to the writer.

#### *Perverted Activity of the Tongue Produces Deforming Strains in the Tooth-bearing Tissues.*

The diagram in Fig. 5 shows the position of the tongue and the muscles chiefly concerned in its upward and forward thrust, a kind of activity that in many young children has been observed, as above stated, to constitute an abnormally large share of the total effort expended in the oral preparation of food. The tongue is drawn forward and pressed against the lingual walls of the upper anterior teeth and anterior surface of the palate chiefly or almost entirely by

FIG. 3.—"Superior protrusion," with the several other abnormalities that are nearly always found associated with that deformity.

the contraction of the genioglossal muscle. Although theoretical consideration of the normal anatomy and physiology of the parts might bar out any dispute upon that point, it may be well to mention in addition the following demonstrable evidence: 1. Subjective experiments by the writer and some others in whom the lower premolars were missing. By inserting a hooked finger at the angle of the mouth the strong contraction of the genioglossal muscle could be distinctly felt whenever the tongue was thrust upward and forward as described. 2. Experiments upon two subjects in whom the symphyseal portion of the mandible had been removed, and as a consequence the tongue (sound and about normal in size) could not be protruded beyond the lips, and even when the tongue was kept inside the mouth no forward pressure could be exerted with it.

FIG. 5.—Diagrammatic vertical section, showing the chief muscles contracted or called into play during the tongue's perverted activity in food "mashing," sucking, &c., and by the reflex pressure incited by sweet (also "sharp," sour, &c.) substances. A backward traction on the mandible takes place and falls upon the frail bony tissues during the "reconstruction" period.

It is clear, then, that by the contraction of the genioglossal muscle the lower jaw is subjected to a backward pull at and about the region of the genial tubercles, which backward traction is abnormal just in proportion as the forward thrust of the tongue is abnormal in force and frequency of action. This backward pull is in daily operation during the four or five years' reign of the deciduous dentition, and, in addition, throughout the period of change to the permanent dentition. During most of that time the horizontal U-shaped cortical tube of a child's mandible is a

frail box almost "cram full" of teeth. Moreover, the strut-and-stay system of trabeculae, the tooth crypts, and to some extent even the cortical bone of the main beam, are undergoing a constant process of breaking down and reconstruction; the alveoli, too, are in turn "swept away"—as Sir C. S. Tomes describes it—and rebuilt. Even in the completed jaw bone of the adult the long-continued action of abnormal stresses brings about bending and shearing strains that in time appear as obvious deformities; the striking deformity observed (in the horizontal branch of the mandible) in some cases of ankylosis has been attributed by Dr. M. H. Cryer to the abnormal action of the depressor muscles, the power of which is, nevertheless, thought to be fractionally small compared with that of the elevator muscles. The more readily, then, will one admit that during the growing and reconstruction period the reaction of the mandible to abnormal stresses may take effect both in inhibiting and disorganising growth and producing durable strains (deforming changes of shape) whenever the stresses exceed certain limits of force and time (or frequency) of action. These limits are known to be low for young children; in the routine practice of orthodontics they are purposely overpassed by the artificial application of very small forces.

I have estimated quantitatively the force of the tongue's upward and forward thrust, and although my measuring apparatus is too crude and imperfect to warrant presenting figures, I am quite satisfied that this force is many times greater in amount than that effectively used by dentists to move teeth and alveoli—often, too, in the permanent dentition.

Those who regard with some doubt the various explanations that the mandibular retrusion is due to "want of development," "heredity," "small tongue," and other

suggested factors that are ill-defined and mostly negative, will be glad to turn to the consideration of a positive factor that can be seen in action, that acts in the precise direction required to produce the observed phenomena, and the more hidden results of which in changing the normal disposition of the bony tissues can be further investigated by X ray examination and also in the dissecting room.

In some cases it may be that the backward or centripetal pull of the genioglossal and "sublingual" muscles produces retrusion of the mandible solely or mainly by inhibiting or restraining its development. But to deny or exclude the possibility of actual deforming strains (that is, slow yielding of the bony tissues) occurring, would be to make a unique exception of a particular part of the jaw and to endow it with an unknown super-resistant quality. And if growth-inhibition or yielding from backward traction did in point of fact occur, the resulting deformities would be exactly like those that confront us daily and with increasing frequency, and that, in this country alone, must affect many thousands of children in whom the handicapping disorder will not be treated or ever right itself.

I turn now to the *excessive overlap* or (what is practically the same thing) abnormally high level of the incisive border of the mandible. The majority of observers are agreed that the causes of this very common deformity, by no means confined to superior protrusion cases, "remain shrouded in sphynx-like mystery." Explanations such as "pressure of the lower lip," "eruptive pressure of the canines" have been somewhat waveringly offered, and in application to but a few cases only; the explanation I here advance applies to a wide range of cases, possibly to nearly all cases of excessive overlap.

The diagrams, Figs. 1, 5, and 6, help to show that the part of the tongue whereat (during eating, sucking, &c.) pressure is applied against the palate and anterior upper teeth lies at a *higher level* than the bony area of attachment of the genioglossal muscle. There-

fore in the resistant pull of this muscle upon the tongue there must be a *downward* as well as a backward component, the general substance of the tongue being at the same time stiffened to a quasi-rigidity by a number of other muscles, the coördinated actions of which it is needless at present to analyse. When holding the raised tongue against the resistance offered on or at the anterior maxillary surfaces, the genioglossal fibres are perforce inclined markedly upward, so that (reaction being equal and opposite) their contraction must exert an obliquely *upward* and backward pull upon their place of origin on the mandible. The existence and the strength of this upward pull can be felt and realised when (under the conditions described), with an inserted finger, an

FIG. 7.—Diagram showing that the resistive reaction to the upward thrust of the muscle-stiffened tongue must involve a downward pressure upon the mylohyoid, thus causing a downward and (narrowing) centripetal pull upon the inner surfaces of the mandible.

attempt is made to press or keep the converging anterior part of the muscle down. Under this upward tensional stress the young "unready" bone is strained and very slowly and gradually yields in an upward direction. The force of the pull is distributed on and about just that very region where the apices of the milk anterior teeth and the crypts of the permanent ones lie, so that it would undoubtedly tend to produce the unexplained variety of phenomena found associated with uprising of the alveolar border—"apical crowding" and anterior "crowding" with or without spacing of the crowns, the "fan" arrangement, and the (hitherto) completely puzzling type mentioned by Sir Harry Baldwin, wherein the lower incisors "were jumbled together into two lines."

And the "low level" of the mandibular post-canine teeth is a further and almost inevitable consequence ensuing from the downward component of the tongue's pressure upon the diaphragmatic floor of the mouth, whereon the base of the muscle-stiffened tongue finds the necessary resistance to its own upward thrust. The digastric and geniohyoid muscles play a considerable part in supporting the upward thrusting tongue, but certainly the mylohyoid "slings" upon which the tongue is seated must exert a downward pull upon those inner surfaces of the mandible from which they are hung. (Fig. 7.) Experimental trial (subjective and objective) readily shows that in reaction to the tongue's upward thrust the downward bulge of the oral floor is both seen and felt to be lowest or most prominent in the region of the lower premolars and first molars, where, as it happens, the "low level" of the alveolar border or teeth is found to be the most marked. It is worth noting, too, in view of the downward traction internally, that the mandibular cheek teeth often have an abnormally inward tilt.

The pull of the mylohyoid (under the tongue's perverted activity) will of course vary in strength and direction with the individual, and with the varying proportional development of the different tissues, including the tongue itself. So that when the tongue is (constitutionally?) small and narrow, the supporting mylohyoid sheet may attain a more nearly horizontal plane and its pull will then be the more directly *inward*, tending to draw the two sides of the mandible together. Thus if a tongue small or subnormal in volume is found associated with a narrow arch, the usual explanation that the small tongue (negatively or by its passivity) causes the narrow arch may be wrong, and is based too much upon assumption. The significance, if any, of the association can be more instructively interpreted by taking into account the more horizontal direction of the

FIG. 6.—To illustrate, in simpler diagram, the conditions detailed in Fig. 5.

contractile pull of the mylohyoid upon the mandible. A large tongue will, on the other hand, the more deeply bulge into and fill the oral floor-space, partly overcoming the resistance of the mylohyoid sheet and causing its pull upon the mandible to be more downward and less inward. In regard to the inward traction the following observation may be significant.

During the routine examination of many thousands of occluded plaster casts, I observed that in a proportion of those in which the occlusion of molars might be reckoned as good mesio-distally the occlusion bucco-lingually would have been better or more normal if the mandibular molars were moved buccally or wider apart—that is to say, the mandibular arch was a little too narrow at the first molars for the normal occlusion of these teeth with their maxillary opponents. This in itself suggests the possibility that in some cases the *lower jaw leads the way* in the contraction of both arches.

In conclusion, it is urged that what I have called (in short phrase) “perverted activity of the tongue” is harmfully frequent among children, and is incited chiefly in the oral manipulation of foods a *preponderant* amount of which is of a sweet, soft, or glutinous nature; and also less frequently by the crippling or (from whatever reason) insufficient use of the cheek teeth.

At the same time it is possible to go to the other extreme by encouraging young children to masticate well an unduly large proportion of tough food, so that the anterior teeth are to an undue extent called upon to relieve the overworked cheek teeth in the extra labour of fine reduction; the forward-thrusting and holding action of the tongue is thus brought into too frequent use, and the mandible is subjected to an upward and backward traction. In several reported cases (including children of dentists) where the precepts of vigorous mastication were faithfully and conscientiously put into practice, the deciduous arches were seen to be broad and fine, and the teeth individually were in every way satisfactory; nevertheless, the puzzling excessive overlap was there, as well as some degree of post-normal occlusion.

That the forward thrust of the tongue during its perverted activity must, in some cases, induce protrusion of the *upper* teeth is so evident a proposition that I omitted any explicit statement on the point, and detailed discussion is here barred out from want of space. But what I regard as remarkable and important in my discovery (about five years ago) of the tongue's abnormal activity, is its unsuspected yet inevitable reaction on the mandible. The tongue exerts a *centrifugal pressure on the maxilla* anteriorly, and the main resistance and reaction to the tongue's thrust takes effect as a *centripetal traction on the mandible*, the one being in effect the reciprocal of the other.

The great majority of superior protrusion cases are associated with inferior retrusion, as stated by Mr. Norman G. Bennett when reporting (March, 1912) to the British Society for the Study of Orthodontics, for the Committee on Orthodontic Classification. The degree of superior protrusion actually produced during functional activity must depend upon the greater or less amount of counteracting restraint and inward pressure from the upper lip, which effective centripetal pressure varies, I think, not so much or so entirely with the length, thickness, or “poise” of the lip as with the “temperamental” and muscular *motility* in the particular individual. This line of investigation may seem too obscure to bring out anything helpful, but in point of fact striking differences in the functional labial movements of different individuals are made evident merely by visual observation. More important, however, and more directly bearing upon my present thesis concerning the identification of primary causes and the actions they evoke, is the marked influence of *reflex* movement and pressure, here just touched upon as follows:—

#### *Gustatory Reflexes.*

Among the oral *reflexes* incited by sweetened food and sweet substances, as well as substances with an acid or a “sharp” taste, there are certain labial and buccal muscular actions which very probably play a part in the contraction of the upper arch. Discussion of this would be quite relevant, but must be deferred.

I propose in a future communication to show that perverted activity of the tongue may also bear a causal relationship to two other deformities of the jaw—namely, (1) inferior protrusion or “underhung” bite; and (2) open bite.

## I.—THE ANTISCORBUTIC AND GROWTH-PROMOTING VALUE OF CANNED VEGETABLES.

BY MABEL E. D. CAMPBELL AND HARRIETTE CHICK.

(From the Lister Institute, Department of Experimental Pathology.)

THE experimental work described below was undertaken in August, 1918, at the request of the Controller of Horticulture, Food Production Department, and Miss Campbell, of that department, was detailed to work upon this problem at the Lister Institute. It forms one of a series of researches on experimental scurvy carried out at this Institute. The aim was to ascertain what changes take place in the nutritive value of vegetables during the process of canning, with special reference to vitamin-c content.

It was to be presumed, from the information already available as to the destructive effect of heat upon the antiscorbutic factor in cabbage leaves (Delf, 1918), that canned vegetables would suffer considerable deterioration in antiscorbutic value owing to the high temperature to which they are exposed in the process of preparation. The present work was directed to obtaining an accurate estimate of what that loss might be. (Cabbage and green (runner) bean pods were selected as suitable vegetables for the experiment.) Cabbage was chosen because many data as to its antiscorbutic value, both in the raw and cooked condition, were already available from the researches of Dr. Marion Delf (1918) at the Lister Institute; green runner beans because they are a good example of a vegetable frequently chosen by the public for preservation by canning.)

The experiments consisted essentially in estimating and comparing the minimal amounts of these vegetables—(a) when raw, and (b) after canning—which must be added daily to a basal scurvy-producing diet in order to protect young guinea-pigs from scurvy over a period of three months. These results are set out in the accompanying table, in which data obtained with other foodstuffs are included for purposes of comparison.

#### *Method of Experiment.*

The method of experiment was the same as that adopted generally in the series of researches on experimental scurvy published from this Institute.<sup>3-10</sup> It is based on that employed by Holst and Fröhlich,<sup>12</sup> who chose the guinea-pig as experimental animal and grain of various kinds with water as the basal “scurvy diet.” On such a diet young guinea-pigs are found to sicken and die of scurvy in from three to four weeks with great loss of weight.

In a study of the anti-scurvy value of foodstuffs the aim is to devise a diet which shall afford abundance of all necessary factors except the antiscorbutic factor. This basal diet must contain suitable proportions of (a) carbohydrate and (b) fat, the right kind and amount of (c) mineral salts and (d) protein, and in addition an adequate quantity of the two so-called growth accessory factors described by McCollum and his co-workers as (e) “fat-soluble” growth factor and (f) “water-soluble” or antineuritic (antiberi-beri) factor. In the diet of oats, bran and water which we have employed in many cases (a), (b) and (f) are provided in sufficient quantity and probably in the mixture of the two grains, oats and wheat (c) and (d), are also adequate for the nutrition of the guinea-pig. The diet is, however, deficient in both the anti-scurvy factor and the “fat-soluble” growth factor. (It has therefore been our practice in many experiments to supply the latter by means of a daily ration (60 c.cm.) of milk heated for one hour to 120°C. to destroy its original antiscorbutic properties. This addition also affords an extra supply of protein of a highly nutritious character, and upon this “scurvy diet” the animals grow well until loss of weight sets in with the occurrence of scurvy symptoms. Death from scurvy occurs in from four to six weeks.)

By addition to the basal diet of various weighed daily rations of (a) raw beans and canned beans, (b) raw cabbage and canned cabbage, the minimal amounts required to protect from scurvy were estimated. On comparison of these values the degree of destruction experienced by the antiscorbutic factor during the process of canning and storage could be approximately determined.

weighed amounts of the vegetables (cut into small pieces) were offered to the animals daily. Usually the ration was consumed greedily, but any residue noted on the next day was weighed (after soaking in water) and the amount deducted from the original weight given. If a residue was found on several succeeding days the animal was rejected, as hand-feeding of soft vegetables is too laborious and inaccurate a procedure. While animals were developing scurvy, hand-feeding of milk with a glass syringe was frequently resorted to in order to maintain an average consumption of 60 c.cm. daily.

namely, 2-3 months. All canned samples were drained and turned out into a dish immediately on opening the can. The residue not used for the day's ration was kept in cold store. It was rarely used later than two days after opening.

**Cabbage**—(1) *Antiscorbutic value*.—In this case the experiments were arranged to test the canned material as fresh as possible; it was never more than three weeks old, and the average age was two weeks. Previous results obtained by Dr. Marion Delf (1918) showed that 1.5 g. of raw cabbage added to a diet of oats, bran and autoclaved milk sufficed to prevent scurvy in young guinea-pigs, but that

\* Equivalent to 50 g. fresh cabbage.

#### Methods Employed in Canning.

**Cabbage**.—The methods used were those advocated by the Food Production Department in their pamphlet No. 34. Fresh green outer leaves were chosen. These were washed in cold water, blanched, and cold-dipped (i.e., exposed to boiling water containing a little sodium bicarbonate for 3 minutes, then plunged into cold water), and packed into lacquered cans. These were filled with boiling water to within  $\frac{1}{4}$  inch of the top, and at once hermetically sealed by soldering the lids. Sterilisation was effected by exposure of the cans to steam at 100° C. for 1½ hours in a closed boiler. After cooling by plunging into cold water the cans were stored at laboratory temperature (60-65° F.). Experiments with control tins in which the lids were replaced by corks carrying thermometers showed that this process of canning involved the exposure of the cabbage in the cans to a temperature of 90-100° C. for 1 hour. The average proportion of cabbage to water in the cans was found to be 1.6 to 1.0 by weight and the water content of the drained cabbage as fed to the animals, 90-92 per cent., was approximately the same as that of fresh cabbage. The approximate mean age when tested was two weeks after canning.

**Beans**.—Young crisp runner bean pods were selected where possible. The method in outline resembled that used with cabbage, with the difference that the blanching lasted 4 minutes, and the sterilising was done intermittently—i.e., for 1½ hours on one day and 1 hour on the succeeding day. Control experiments showed that the contents of the cans were exposed to a temperature of 100° C. for a total period of approximately 2 hours 20 minutes. The proportion of beans to water was approximately 1.7 to 1.0, and the water content of the canned samples 94-96 per cent. The time of storage at laboratory temperature before testing of the canned beans was longer than was the case with the canned cabbage,

0.5 g. daily was insufficient for that purpose. With 7.5 g. daily of canned cabbage growth was well maintained in three animals, and there were no symptoms of scurvy during life or post mortem. With a 5 g. ration daily, good health was enjoyed by two animals out of three, but in these cases distinct signs of scurvy were shown by soreness of the limbs and characteristic hæmorrhages post mortem. The third animal developed severe scurvy during life and showed the usual signs at post-mortem examination. Although these animals showed good health in two cases out of three the degree of protection from scurvy was less than that enjoyed upon a 1.5 g. ration of raw cabbage; it was, however, distinctly greater than upon a 0.5 g. ration. The loss of antiscorbutic value during canning would, therefore, appear to be about 70 per cent.—i.e., an antiscorbutic value of 5 g. raw cabbage was reduced to that of about 1.5 g. raw cabbage.

(2) *Growth-promoting value*.—In a further set of experiments an attempt was made to trace the fate during canning of the growth-promoting "fat-soluble" accessory factor known to be present in green leaves (McCullum, Simmonds, and Pitz, 1916). The ration was much increased—viz., to 15 g. daily—and autoclaved milk, which provided the "fat soluble" growth factor in the preceding experiments, was omitted from the dietary, which consisted therefore of oats and bran alone. Delf (loc. cit.) has shown that a diet of oats and bran and 15 g. of raw cabbage is sufficient to promote good growth and provide ample protection from scurvy. This ration of fresh green leaves provides a large excess of the antiscorbutic factor, and is evidently also large enough to afford the necessary fat-soluble growth factor and to supplement any defect in the nature of the proteins in oats and bran, if such exists. After heating in steam for 1-2 hours at 100° C., Delf found the same ration, 15 g., adequate for

the purpose; the animals were maintained in good health, and in one case healthy young were born.

In the case of canned cabbage, also employing a 15 g. ration, the result was otherwise. Scurvy was certainly prevented, but the animals showed little or no growth during the three months of the experiment. In the case of one animal autoclaved milk was provided from the sixty-fourth day, and growth immediately began. This result suggests that during heating and storing in water the growth-promoting vitamin originally present in the green leaves was either (1) destroyed to a large extent, or (2) had escaped into the water in which they had been immersed (the proportion of cabbage to water by weight in the cans was approximately 3:2). A series of further experiments was made in which the water in the tins was fed to the animals, together with the canned cabbage; much better growth was obtained, a result which seems to support the second view.

In the experiments described in the preceding section with smaller rations of canned cabbage, 5 to 7.5 g., the "fat-soluble" growth-promoting factor was provided in the ration of autoclaved milk.

**Beans.—Antiscorbutic value.**—There are no quantitative data available as to the antiscorbutic value of the raw runner bean pods in comparison with other vegetables. Special experiments had therefore to be made in order to determine the minimum amount which must be fed daily to guinea-pigs on a scurvy diet in order to prevent onset of the disease. They showed that a 5 g. ration may be taken as the minimum amount giving protection from scurvy. With 2.5 g. and less all animals developed the disease, and with 5 g. and over all escaped. After canning, however, a daily ration of 20 g. was found inadequate, and severe scurvy was developed in every case. *By the process of canning, therefore, the antiscorbutic value of 20 g. raw bean pods was reduced to less than that of 5 g., and was not superior to 1.5 or 2.5 g. raw bean pods—in other words, 75 per cent. to 90 per cent. had been destroyed.*

#### Conclusion.

1. In the process of canning vegetables the greater part of the original antiscorbutic value of the raw vegetable is destroyed. In the case of runner bean pods the loss is estimated at about 90 per cent. of the original value; in the case of cabbage at about 70 per cent. of the original value. The process of canning cabbage included heating in water for about one hour at 90° to 100° C., and for beans the process was repeated on the day following.

2. This loss is primarily due to the destruction of antiscorbutic material occurring during the heating involved in the process of canning. A further loss may be expected to take place during the period of storage. The canned cabbage was examined two weeks after preparation and the canned beans three months after.

3. In the case of green-leaf vegetables which possess, in addition to the antiscorbutic vitamin, the "fat-soluble" growth-promoting accessory factor, the latter substance is also lacking in the canned material unless the liquor be also taken.

4. The value of canned vegetables as regard antiscorbutic and growth-promoting properties must be regarded as negligible.

## II.—THE ANTISCORBUTIC VALUE OF SOME INDIAN DRIED FRUITS:

(a) TAMARIND, (b) COCUM, AND (c) MANGO ("AMCHUR").

BY HARRIETTE CHICK, E. MARGARET HUME, AND RUTH F. SKELTON.

(From the Lister Institute, Department of Experimental Pathology.)

THE experimental investigation of these dried fruits was undertaken early in 1917, at a period in the war when scurvy was still proving a serious menace to our native troops in Asia. These and similar materials have long been esteemed as antiscorbutics by the native population of India,

and instances are to be found in the literature and elsewhere in which the prevention and cure of human scurvy has been attributed to their agency. For example, MacNab<sup>1</sup> (1837) relates how an outbreak of Scurvy at Nassirabad, Rajputana, in 1833-34 was treated with good results by an infusion made from "anola," the dried fruits of *Phyllanthus emblica*. This product was commonly bought and sold in the native bazaars and considered to possess great antiscorbutic virtue. The dose taken amounted to ½ oz. (14 g.) daily, calculated on the original dry material.

Major-General Sir Havelock Charles,<sup>2</sup> who was attached as medical officer to the Afghan Boundary Commission in 1884-86, ascribes the freedom from scurvy of the native troops accompanying this expedition to the regular consumption of "amchur," or dried mango, whenever fresh fruits or vegetables were unavailable. It was at his suggestion that we undertook the following experimental study, and the samples of tamarind, cocum, and amchur investigated were obtained from India with his assistance. Of these, the two first-named are commonly included in the native soldiers' ration.

The method adopted for studying the antiscorbutic value of these fruits was as follows. Guinea-pigs were used as experimental animals, following in principle the methods employed by Holst and Fröhlich<sup>3</sup> as modified by Chick and Hume.<sup>4</sup> If greenstuff is removed from their normal diet of grain and green leaves these animals sicken and die of scurvy in 3-6 weeks. In the present experiments the basal "scurvy" diet consisted of oats and bran *ad libitum*, together with a daily ration of 60 c.cm. of milk, heated to 120° C., for one hour to destroy its original antiscorbutic value. This diet is satisfactory for the nourishment of these animals in every respect save only that it lacks the antiscorbutic vitamin. Good growth is made until the onset of scurvy. The antiscorbutic value of any foodstuff is determined by observing the effect of adding measured daily rations to the basal diet and estimating the average minimum daily addition necessary to prevent scurvy.

*Antiscorbutic Value of Dried Tamarind, Cocum and Amchur, compared with other Fruits and Vegetables in the Fresh Condition, based on Experimental Work with Guinea-pigs.*

Basal diet: Oats and bran *ad libitum*; autoclaved milk, 60 c.cm. daily.

Antiscorbutic material.	Dose.	No. of animals.	Time of experiment.	Result.
None.	—	4	days.	Death from scurvy in 4-6 weeks.
Tamarind	3.5 g.	4	34-40	Scurvy, but some protection, life prolonged.
Cocum.	4 g.	4	38-91	Scurvy, but some protection, life prolonged in some cases.
"Amchur."	4.5 g.	4	50-71	Scurvy, but some protection.
Fresh meat juice, raw.	20 c.cm.	4	29-66	Scurvy, slight protection in some cases, life prolonged to 9 weeks in 1 case.
Beetroot juice, raw.	20 c.cm.	2	67-88	Scurvy, slight protection only.
* Carrot juice, raw.	20 c.cm.	4	53-95	Protection from scurvy.
* Swede "	2.5 c.cm.	4	90-100	
* Cabbage leaves.	1.5 g.	6	70-90	
* Germinated peas.	5 g.	5	87-97	
* Green bean-pods (scarlet runner).	5 g.	3	84-91	
* Fresh lemon juice.	1.5 c.cm.	4	90	
*† Fresh lime juice.	10 c.cm.	2	61-93	Protection from scurvy.
* Potato, cooked.	20 c.cm.	3	73-92	

\* Minimum doses required for prevention of scurvy.

† Sour lime, West Indian.

The investigation of these dried fruits presented great technical difficulty, as the animals could not be induced to eat them in the dry condition. It was necessary to make decoctions by soaking in water and squeezing the pulp through muslin and hand-feeding the thick liquor obtained to the animals by means of a syringe. Even so it was distasteful, and there was a limit to the amount that could be tolerated. The daily doses shown in the accompanying table, 3 to 5 g., are calculated in terms of the original dry material, and represent the largest amounts it was found possible to administer.

With these doses there was evidence of a small but distinct protective action. This action was not complete, and scurvy occurred invariably, but a fair measure of health and growth was apparent, and in some cases life was prolonged for as long as three months. Animals surviving this period were killed by chloroform and post-mortem examinations were made.

In absence of any addition to the "scurvy" diet, death from severe scurvy took place in 30-40 days, and there is little doubt that had it been possible to administer larger amounts a more complete protection from scurvy would have been obtained.

In the accompanying table are given also the minimum amounts of other foodstuffs required to prevent scurvy under similar conditions for purposes of comparison. It will be seen that the value of these dried fruits is much inferior to that of many vegetables and fruits (cabbages, swedes, germinated pulses, oranges, lemons); is equal or superior to others (carrots, beetroot), and to meat juice.

#### Conclusion.

Dry tamarind, cocum, and mango possess a definite but small antiscorbutic value. This value is greatly inferior to that of raw cabbages, swedes, germinated pulses, orange juice, lemon juice, but equal or superior to that of carrots, beetroots, cooked potatoes, raw meat juice, reckoned weight for weight in the natural condition.

### III.—A COMPARISON BETWEEN THE ANTISCORBUTIC PROPERTIES OF FRESH, HEATED, AND DRIED COW'S MILK.

By ROSAMUND E. BARNES AND E. MARGARET HUME.

(From the Lister Institute, Department of Experimental Pathology.)

In previous communications, one of us (E. M. H.), in conjunction with Chick and Skelton (1918, I. and II.), has shown that raw cow's milk must be classed among the less valuable foodstuffs as regards its antiscorbutic properties. Whereas in the case of many raw fruits and vegetables, amounts varying from 1.5 to 10 g. daily will prevent scurvy in guinea-pigs upon a diet otherwise devoid of antiscorbutic material, 100 to 150 c.cm. of raw cow's milk is required. The present work, which will shortly be published in greater detail in the *Biochemical Journal*, consists of an attempt to make a direct comparison between the antiscorbutic value of dried and raw milk, in order to ascertain to what extent, if any, the former is inferior.

#### Inferiority of Dried Milk.

Two series of experiments were made, one series with guinea-pigs and the second with monkeys, young growing animals being selected in both instances. In each series the same result was obtained, showing the marked inferiority of

the dried milk for the prevention of scurvy. The dried milk used was a well-known commercial brand manufactured by the Just Hatmaker process. Two sets of samples were tested: Sample A was delivered regularly immediately after manufacture and was less than three weeks old when used for experiment; Sample B was 6 to 12 months old when tested. The fresh milk used for comparison was very pure, specially delivered, country milk, obtained from a model dairy. The methods adopted in the experiments were the same as those previously described by Chick, Hume, and Skelton (1918, II.).

The results obtained with raw milk confirm those of the earlier work, 100 to 150 c.cm. daily being found necessary to prevent scurvy in animals of 300 to 500 g. weight. In case of the dried milk these amounts proved inadequate, and every animal developed the disease after periods of time varying from 20 to 30 days. These experiments with guinea-pigs are extremely difficult to carry out, as comparatively few animals of this size are able to tolerate these large amounts of fluid without digestive disturbance. For this reason the animals receiving dried milk were at an advantage, because it could be given in a concentration greater than that of ordinary milk and the quantity of fluid taken could thus be lessened. The results of these experiments are summarised in the table (A).

The monkeys used in the second series of experiments were a varied collection. In all 8 animals were used, including the following genera: macacus, 2 species; cercopithecus, 2 species; cercocebus, 1 species, of weight varying from 2 to 3 kilograms. The results are summarised in the table (B) and completely confirm those obtained with guinea-pigs. In case of raw milk a ration of 125 to 175 c.cm. daily was found adequate to maintain health and to prevent scurvy; but with dried milk severe scurvy was developed on daily amounts equivalent to 200 c.cm. and a ration of about 250 to 300 c.cm. was found necessary for safety. The dried milk used in these experiments was all taken from Sample A, and fed less than three weeks after manufacture.

With animals so few and so various there was danger of drawing erroneous conclusions due to idiosyncrasy of individuals, but this was avoided by observing the effect of fresh and dried milk upon the same animal. Thus monkey No. 6 in the table (B), which acquired severe scurvy on a daily ration of dried milk equivalent to 175 c.cm., was cured completely when a daily average of 175 c.cm. fresh milk was substituted for the dried milk ration. In fact, this animal remained in good health during a long subsequent period, when this amount was cut down to 125 c.cm. daily.

#### Value of "Scalded" Fresh Milk.

Monkey No. 7 had developed severe scurvy when receiving a daily ration of dried milk equivalent to 200 c.cm., and had shown no improvement, but grew progressively worse when this was increased to 300 c.cm. daily. The milk ration was then changed to 200 c.cm. daily of "scalded" milk—i.e., milk brought rapidly to the boil in a saucepan over a gas-

TABLE SHOWING ANTISCORBUTIC VALUE OF COW'S MILK, FRESH AND DRIED AND HEATED.

#### (A) Experiments with Guinea-pigs.

(The Diet Consisted Otherwise of 10-21 g. Oats and Bran.)

(1) No. of animals used. (2) Average amount consumed daily (c.cm.). (3) Time of experiment (days).

Description of milk.	(1)	(2)	(3)	Result.
Fresh milk, full cream or separated.	6	113	36-111	Death from scurvy in 1 case. Death from other diseases in 2 cases, one showing slight traces. Scurvy post-mortem. Good health in 3 cases.
Dried milk, full cream, 1-2 weeks after manufacture.	5	108*	25-48	Scurvy in all cases, very severe in 4 cases.
Dried milk, full cream 6-12 months after manufacture.	5	97	33-72	Scurvy in all cases, severe in 4 cases.

#### (B) Experiments with Monkeys.

(The Diet Consisted Otherwise of Boiled, Polished Rice, Wheat Germ, Pea Nuts, Dried Peas.)

(4) No. of monkey. (5) Average daily ration milk (c.cm.). (6) Time of experiment (days). (7) Time after which onset scurvy observed (days).

	(4)	Wt. (g.).	(5)	(6)	(7)	Result.
Fresh raw milk.	1	2089	50 (maximum)	150	66	Scurvy.
	2	2770	75	143	119	Scurvy, cured with 10 g. daily raw germinated peas. Good health.
	3	1940	125	182	—	Inconclusive result.
	4	2770	150	184	115†	Good health.
	5	2230	200	225	—	Good health.
Dried milk, less than 3 weeks after date of manufacture.	6	2090	175	142	105	Severe scurvy; cure obtained with 175 c.cm. fresh milk daily, consolidated on 125 c.cm.
	7	2470	200-300	104	87	Severe scurvy, cured by 200 c.cm. daily of "scalded" raw milk.
	8	2740	250	161	117†	Inconclusive result.

\* Average taken up to time of onset of scurvy.

† Scurvy symptoms noted, improvement later without alteration of diet, coincident with time of year when cows leave winter stalls for the open pasture.

burner, and then immediately set to cool. This procedure was arranged to imitate, as far as possible, a common household method of boiling milk before feeding to infants, and one that may be relied upon to destroy the tubercle bacillus and other infective disease germs. Measurements of temperature were made, and it was ascertained that during this process the milk was exposed to a temperature between 70° and 100° C. for 1½ minutes during the heating, and 4 minutes during the cooling.

Milk so treated was found to possess an antiscorbutic value much in excess of that possessed by dried milk. A rapid cure was the result of substituting 200 c.cm. of this "scalded" milk for the dried milk ration in case of monkey No. 7. The day after the change was made the animal showed a very slight improvement, and in a week was markedly better; in 16 days he had regained the use of his hind limbs and loss of weight had ceased, and satisfactory growth became established. Two experiments in the table (B) are described as yielding an inconclusive result. In both cases symptoms of scurvy developing on a certain ration of milk, raw in one case and dried in the other, disappeared later without any intentional change in diet. The experiments were started in the winter and scurvy was detected about four months later, in April-May, but soon afterwards the symptoms began to clear up. This we attribute to the change in the cow's diet about this time of year—i.e., from the hay, roots, oil-cake, and cereals of the winter feed to the fresh grass of the open pasture. In consequence of the great increase of antiscorbutic material in the cow's diet, one would expect a corresponding increase in the antiscorbutic value of the milk given:

#### *Summary and Conclusions.*

1. The antiscorbutic value of cow's milk, fresh, heated, and dried, was determined by means of quantitative nutritional experiments with guinea-pigs and monkeys. Cow's milk, even when fresh, was found to be a foodstuff comparatively poor in antiscorbutic properties, and large daily rations, 100 to 150 c.cm. daily for guinea-pigs and 125 to 175 c.cm. daily for monkeys, were needed to protect these animals from scurvy, when upon a diet otherwise devoid of antiscorbutic material. Dried milk was found inferior to raw milk in this respect. Even with material of quite recent manufacture we were unable to protect guinea-pigs from scurvy with any amounts that it was found possible to administer. In case of monkeys the minimum protective dose was found to be approximately from 250 to 300 c.cm. daily; in other words, about half the original antiscorbutic value of the fresh milk had been destroyed in the process of drying. "Scalded" milk was found distinctly superior to dried milk.

2. These facts form a strong argument for the desirability of adding an extra antiscorbutic to the diet of infants nourished on dried milk. The most suitable substances for this purpose are raw orange juice, raw swede juice (Chick and Rhodes, 1918), or juice of tomatoes, raw or canned (Hess and Unger, 1919). Grape juice and carrot juice are also useful but less valuable, as, being inferior in potency, correspondingly larger doses are required. Potatoes cooked and mashed can be employed in cases where starchy foods are not considered unsuitable (Hess and Fish, 1914).

3. Some evidence was obtained showing that winter milk is inferior to summer milk in antiscorbutic properties, corresponding to the differences in the cow's diet at these different seasons. In this connexion the suggestion is made that the value of winter milk in this respect might be raised if swedes were employed for winter feeding in place of mangolds, where possible. In the investigation of Chick and Rhodes alluded to above, the raw juice of beetroot, to which plant the mangold is nearly related botanically, was found to be much inferior to that of swede as an antiscorbutic.

4. No significant difference was detected in the growth-promoting properties of raw and dried milk respectively, and this was true with both guinea-pigs and monkeys. In both cases growth declined with onset of scurvy symptoms, but until this occurred the growth made upon diets containing dried milk was equal to that obtaining when equal rations of fresh milk were substituted.

#### A NOTE ON

### IMMUNISED SKIN-GRAFTS.

BY ARTHUR L. YATES, M.C., M.D. LOND., F.R.C.S. EDIN.

CERTAIN German writers during the war described a process of rendering the skin immune to the toxins present in the wound for which the skin-graft was intended, and claimed that if skin immunised in this way was employed for skin-grafts the growth of epithelium was quicker and more certain than if the usual methods were followed.

#### *Description of the Process.*

The method consists of placing the dressing which has been in contact with the surface of the wound it is intended to treat, and which is therefore soaked in the discharges of the wound, upon an area of skin suitable for obtaining grafts by the Thiersch method and allowing this dressing to remain in position for 24 hours, after which it is replaced by another dressing removed from contact with the wound.

It was found necessary to moisten dressings on which the discharges had dried and to mark out the skin selected for yielding the graft by means of nitrate of silver.

Applied with these precautions, the skin to which the wound discharges were brought into contact was found to redden and to show on the third day of the application a slight prominence of the papillæ. It was necessary to watch the skin carefully at this point in the treatment, as it is of considerable importance to guard against the occurrence of a violent reaction. When the skin showed a marked elevation of the papillæ and slight reddening the treatment of the area was stopped for a day, but in most cases it was possible to treat the skin in this way for a period of seven days, after which the graft was ready for removal.

It was found that the severity of the reaction varied within rather wide limits, and that it was necessary to guard against a violent reaction. In two or three cases no reaction occurred. This was thought to indicate that the skin already possessed immunity to the organisms of the wound, and to a certain extent this view was borne out by the fact that the graft "took" readily in these cases.

#### *Technique.*

I found that the following technique gave the most satisfactory results.

The granulations of the wound were rubbed with dry unmedicated gauze and the graft removed by the method of Thiersch, applied to these granulations, and well pressed down. The graft was then covered with a piece of waterproof tissue, in which a number of holes of about one-eighth of an inch diameter had been cut, and the opposite edges of this waterproof tissue were fixed to the skin with adhesive plaster. This was then covered with unmedicated gauze and wool, and bandaged in position. The wound was examined every second or third day and any discharge removed by gently syringing through the holes in the waterproof tissue, which was not otherwise disturbed.

#### *Results.*

Applied in this way, I have not seen a case of failure by this method, although up till now I have only treated 27 cases, and of these only three were cases that had failed to give a successful result by the ordinary methods. Of these 27 cases, 10 were cases of ecthyma, where deep ulcers had developed and which had resisted treatment for several weeks previously to the grafting, 13 were cases of infected lacerations, where healing was delayed for several weeks, and 4 were cases of chronic ulcer, which had resisted treatment for a long time. In several cases a certain amount of movement of the limb was allowed, and all the cases in which walking with a fresh graft applied to some part of the lower limb was permitted, the graft took without any difficulty.

Local anaesthesia was employed in all the cases, and in the case of ulcers with thickened bases the ulcer also was anaesthetised and the thickened base punctured with a needle in numerous places after the method originally described by Tubby for freeing contracted scar tissue.

Although the character and small numbers of the cases in which I have made use of this method does not permit of any definite conclusion as to the superiority of this method over any previously employed, the method appeared to me to be based on such logical principles and, in the limited number of cases in which it has been tried, to have been so successful that I have ventured to bring it to the notice of those practitioners who did not have an opportunity of seeing the résumé of the original article, which appeared in the "Summary of the Foreign Press" issued to certain medical units of the Army. I regret that I have been unable to obtain the names of the German authors, but the impossibility of obtaining the literature must be my excuse.

Lincoln.

## MUCUS DEPOSIT OF URINE.

By S. G. BILLINGTON, M.B., B.S. LOND.,

LATE CAPTAIN, R.A.M.C.; BACTERIOLOGIST, WOLVERHAMPTON GENERAL HOSPITAL.

If a sample of this deposit in a febrile or convalescent urine be pipetted up from about the junction of the upper and second fourths it will show on direct examination an interlacing mass of strands, many resembling gigantic flagella. These structures are very dim and indefinite, and no satisfactory impression of their form can be obtained except under the low power and with the light, preferably daylight, almost entirely shut off.

If the deposit is washed with filtered water to remove the soluble constituents of the urine the same structures will still be dimly seen; but they at once stand out clearly on adding one drop of 10 per cent. tannic acid to the fluid film, and they will be seen lying in the midst of a coagulated homogeneous material. The structures also take up added watery stains at this stage, although they would not do so before the addition of the tannic acid. If the fluid-stained film obtained in this way is dried while under observation all the structures will be seen to disintegrate as the evaporating line crosses the field of vision.

When fixed and stained the structures show a most extraordinary variation in size and form, and resemble somewhat an interlacing mass of worms. They may be straight, curved, or wavy; some resemble gigantic spirochaetes, others resemble more or less closely enormous trypanosomes or

FIG. 1.—Mucus deposit of urine. Flagellate-like structures lying in masses of coagulated matrix. Stained with methylene-blue.

Leishman-Donovan bodies. Bodies resembling miniature tadpoles with an apparent vacuole at the blunt end are also frequently seen. With the Romanowski stains the blue only is taken up. With Indian ink the general morphology is brought out more distinctly than in stained films, especially as regards the perfect fine flagellate-like extremities and processes.

Under the higher powers these structures appear to be made up of enormous numbers of filamentous strands

Some show darker centres, probably due to contained minute granules, and the forms resembling trypanosomes frequently contain one or more deeply staining bodies about the size of a red blood cell.

### *The Origin of the Deposit.*

As far as I am aware, the mode and site of origin, the significance and the reasons for variation in amount of this substance, are shrouded in obscurity. There are, however, two points of interest. 1. When there is an actual excretion of organisms, as in bacilluria, and a catarrhal condition of the urinary tract may be presumed, the mucus deposit is slight or absent. 2. From chemical examination we are told that this substance in many cases is not true mucin, probably a nucleo-protein. 3. The structures described as being present in mucus deposits vary in size and texture much as in the case of casts. They are much larger and coarser in the urine from a case of febrile or post-febrile trench fever than in the case of influenza.

A year ago the urines of 300 men were examined with regard to the mucus deposit. 200 were patients in hospital

FIG. 2.—Masses of structures in the mucus deposit of urine resembling spirochaetes. Stained with Indian ink.

and 100 were the staff of a medical unit. The urines of the 200 patients all showed a pronounced deposit, and the structures described could be readily seen with the lower power on direct examination. Over 70 per cent. of the controls showed a varying amount of deposit with similar structures. The difference in the bulk of deposit, however, in the two series was extraordinary, and would never have been realised unless series of 20 urines, 10 from patients and 10 from controls, had been placed in line. It may also be added that quite 50 per cent. of the controls had been marked for base duty on account of previous or existing disease of various kinds.

These examinations demonstrated that active disease produces a pronounced increase in the mucus deposit in the urine. In the absence of any definite knowledge as to the origin or significance of the mucus, knowing that the kidneys are the natural filters of the body and the urine the filtrate containing undesirable excreted products, it would not appear to be illogical to suspect that the addition to the deposit represents some form of the infecting agent after excretion.

The presence of spirochaetes in the urine in trench fever and also in normal urine has been recorded on several occasions. One source of these spirochaetes has been found by Japanese workers to be the urethral mucous membrane, and as to that source no comments can be made. The origin of morphologically perfect spirochaetes from the deposit of urine, however, can be directly watched under the microscope. The mucus deposit is washed once, and to a sample on a slide a drop of tannic acid and watery stain are added, as previously described. The film is then gently dried, and as the evaporating zone crosses the field under observation all the large structures mentioned will disintegrate. It will be seen, however, that here and there one of the fine spirochaetal-like processes apparently project beyond the hygroscopic surrounding matrix, and these will be left in the debris as morphological spirochaetes.

## FIVE CASES OF SPONTANEOUS FRACTURE OCCURRING IN SERVING SOLDIERS.

BY C. NOON, F.R.C.S.,

TEMPORARY MAJOR, R.A.M.C.; OFFICER IN CHARGE OF THE SURGICAL  
DIVISION OF THE NORFOLK WAR HOSPITAL.

THE following cases of spontaneous fractures were admitted to the Norfolk War Hospital between November, 1916, and February, 1919. They illustrate some of the most important causes of pathological fractures of bones. They all occurred in serving soldiers. The information with regard to the diagnosis and treatment of spontaneous fractures to be obtained from the ordinary text-books on surgery is extremely brief and scanty. A study of these cases shows how important it is to make a most complete and careful examination of a patient suffering with a fractured bone.

### *Osteomyelitis Fibrosa (Medullary Fibromatosis) of the Right Humerus; Spontaneous Fracture; Union of the Fracture.*

CASE 1.—W. G. J., a private, aged 19, was transferred to the Norfolk War Hospital on Jan. 28th, 1916, complaining of an injury to the right arm. The history of the patient's present condition was as follows. He stated that he had always been a healthy youth, and had suffered with no previous illness, except that he had twice previously met with slight injuries to the right arm, which had resulted in fractures. The arm was "set" by a doctor, and on both occasions after rest in splints it united. The first fracture occurred at the age of 14, and resulted from throwing a cricket-ball. A year later he again broke the same arm by falling off a bicycle. In December, 1915, at the age of 19, his arm was again broken while driving a horse and cart, a sudden jerk of the reins causing the fracture. As far as he was able to judge all the other bones of his body were natural and quite strong. No other members of his family, as far as he could tell, had ever suffered with repeated fractures. His father and mother were both quite healthy.

*Condition on admission.*—The patient was a well-developed healthy youth; temperature normal; pulse-rate 80 per minute. Pupils equal and reacted normally to light and accommodation; teeth good and quite clean; no discharge from ears. Chest, heart, and lungs natural; abdomen natural.

The muscles of the upper arm and forearm were wasted, but the hand muscles were natural. There was a slight angular deformity and swelling in middle third of upper arm. The elbow could not be completely flexed or extended. On palpation there was a well-marked thickening in the middle third of the humerus; the swelling was tender to touch, hard, and felt bony, and could not be distinguished by palpation from callus formed around a uniting fracture. Crepitus could not be obtained, but there was abnormal mobility to be felt in middle third of humerus. There was half an inch of shortening of the right upper arm. The axillary glands were not enlarged. The sensation of the arm and hand was not impaired.

X ray examination showed a fracture through middle third of right humerus. In this situation there was a spindle-shaped enlargement of the bone. In the interior of the bone the osseous tissue had been replaced by clear areas which, from their even contour, sharp definition, and translucency, suggested the presence of cysts. X ray examination of the other bones of the body did not reveal anything abnormal. Wassermann reaction was negative.

*Treatment.*—The fracture was treated by the usual method of splinting protection and massage. It united rather slowly, but except for rather an excessive amount of pain, felt especially at night, at the seat of injury the broken bone did not behave in any abnormal way, in spite of the disease at the site of fracture.

*Remarks.*—The two main factors for consideration in this case were, firstly, the diagnosis and, secondly, the correct treatment. In considering the diagnosis, the points of importance are the age of the patient and the long duration of the disease—five years almost excludes the possibility of malignant disease.

"The diagnosis from other chronic affections of bone was readily made with the assistance of skiagrams. These showed that the contour and architecture of the bones were greatly altered; there was a localised increase in the girth; the surface of the bone was uneven, and in the interior the osseous tissue had almost disappeared, and there were clear

areas which, from their even contour, sharp definition, and translucency, suggested the presence of cysts." (Thomson and Miles.)

With regard to treatment the affected bones should be protected from injury. If fractures should occur every attempt must be made to prevent deformity, and to fix the parts by the aid of splints for a considerable time. Union will generally take place, but will be slow, and repeated fractures are likely to occur. It is improbable that any operative procedure on the fracture will meet with good result, but scraping away the disease from the interior of the bone where there has been no fracture may sometimes be followed with good results.

### *Multiple Gummata of the Bones of the Left Foot; Spontaneous Fractures; Improvement.*

CASE 2.—J. C., aged 41, was admitted to the Norfolk War Hospital on Nov. 29th, 1917, complaining of swelling of the left foot. The history of the present condition was as follows. The patient had been in his usual health until about two months ago, when he noticed swelling of the left foot. This was increased by exercise, and he was unable to march. He had been serving in the Army for three months before he noticed the disability. The condition of the foot had caused him little pain, but he had noticed sharp pains shooting down both legs for the last three or four months. He had contracted syphilis 19 years ago, for which he was treated.

*Condition on admission.*—The patient was a fairly healthy looking man. Temp. 98.4°. Special senses, such as hearing, smelling, tasting, and seeing, normal. Pupils unequal, the right did not react to light and left pupil sluggish, but a faint reaction to light could be obtained. No nystagmus. Disc normal; no squint on narrowing of palpebral fissure. Nothing abnormal discovered on examination of remaining cranial nerves. No paralysis or spasm of any of the muscles of arms or legs and no incoördination. Dullness of sensation over both legs and feet, but no absolute loss of sensation. Sensation to heat and cold normal. Knee-jerks present, but no ankle clonus and no Babinski sign. No wasting of muscles of arms or legs. No loss of control over sphincters. Memory and mental power apparently normal. Chest, heart, and lungs natural; abdomen natural.

*Local condition.*—The skin over the left foot looked natural, but the foot was swollen and pitted on pressure. Well-marked flat foot. The dorsum of the foot looked unduly prominent. There was little or no pain on manipulation of the foot. The bony point could not be easily palpated, owing to swelling and thickening of tissues. No crepitus could be obtained.

X ray examination showed the bones of the foot rarefied. All metatarsal bones were fractured at their base. There was some evidence of new bone formation around seat of fracture. Wassermann reaction was negative.

*Treatment.*—The patient was put on a course of potassium iodide and mercury, given by the mouth. The fractures were treated by the application of splints, rest, massage, and electrical treatment. Great benefit followed these lines of treatment. There was great improvement in the general condition of the patient. Locally the condition of the foot improved and the fractures united.

CASE 3.—J. M., a private, aged 38, was admitted to the Norfolk War Hospital complaining of swelling of the left foot. The history of the present condition was as follows. The patient stated that he was quite well until early in September, 1918; he then twisted his foot on parade and noticed that when he removed his boot the same evening the foot was swollen. He was unable to get his boot on next morning and the foot remained painful for four or five days. He also experienced shooting pains in the left leg as far as the knee. Walking increased the pain in the leg and discomfort in the foot. The swelling gradually subsided, but some deformity and swelling still persisted.

*Previous history.*—The patient said that he suffered with gonorrhoea in 1901, whilst he was stationed in Ireland. He was treated successfully for several weeks. In 1915 he trod on a nail. It entered the sole of the foot in the situation of the head of the fifth metatarsal bone. The wound suppurated, and an operation was performed to drain an abscess. After the operation the wound healed well, and he recovered with complete use of the foot. He stated that he had never suffered from syphilis.

*Condition on admission.*—The patient was a healthy-looking, well-nourished, and muscular man. Temp. 98°; pulse 80. He answered questions with intelligence. The special senses appeared normal. Eyes: pupils unequal, right dilated, left contracted, both reacted sluggishly to light and accommodation. No squint and no nystagmus, fundus was natural, tongue protruded straight, tremulous, and furred; fauces natural. The remaining cranial nerves were normal.

No paralysis or spasm of any of the muscles of arms or legs and no incoordination. Dullness of sensation over both legs and feet, but no loss of sensation to heat and cold. Knee-jerks exaggerated, especially on left side. Babinski's sign well marked in left foot and present, but less well marked, in right; no ankle clonus.

*Examination of left foot.*—The skin over the left foot looked natural, but the foot was swollen and oedematous, the dorsum being unduly prominent. The normal arch of the foot had disappeared, and there was well-marked flat foot. There was little or no pain on palpation. The bony points of the foot could not be easily felt owing to swelling and thickening of tissues. On deep palpation in the region of the base of the first metatarsal bone crepitus could be obtained, but manipulation produced very little, if any, pain.

On X ray examination of the left foot the tarsal bones were found to be rarified. There was a fracture in the situation of the base of the first metatarsal bone. In the situation of the fracture there was marked destruction and absorption of bone, and around the fracture some evidence of new bone formation. There was also a fracture of the second and fifth metatarsal bone, with marked absorption of bone. Wassermann reaction (blood) was positive.

*Treatment.*—The patient was given a course of potassium iodide—20 gr. three times daily for six weeks—and mercury by the mouth. The fractures were treated by splints, rest, massage, and electrical treatment. Great benefit was derived from the treatment, both generally and locally. The fractured bones united.

*Remarks on Case 2 and 3.*—Case 2: There was a definite history of syphilis, but the Wassermann reaction was negative. Case 3: Syphilis was denied, but the Wassermann reaction was positive, and the signs and symptoms of the case were such as to justify a diagnosis of syphilis. A diagnosis of gummata osteitis was considered to be the condition from which both patients were suffering. Both showed symptoms and signs of tertiary syphilis, and both showed marked signs of improvement on the administration of active syphilitic treatment.

*Chronic Suppurative Otitis Media; Abscess of the Thigh; Bony Swelling of the Right Femur; Spontaneous Fracture of the Second Metatarsal Bone of the Left Foot.*

CASE 4.—A. R., a private, aged 19, was admitted to the Norfolk War Hospital on Nov. 22nd, 1918, complaining of a painful swelling in the right thigh and swelling of the left foot. The history of the present condition was as follows. The patient said that he was quite well ten days previously. For the last week he had had pain and swelling of the right thigh. This had gradually got worse—he could not account for the swelling, as there had been no injury. The left foot became swollen three days previously, when he reported sick, and since then had been painful. Had had discharging ears as long as he could remember.

*Condition on admission.*—The patient was an ill-developed and badly nourished youth, who looked ill and pale. Temp. 99°; pulse 80. Very deaf, profuse discharge from both ears, no mastoid tenderness. Eyes natural, teeth very bad, many carious. Chest, heart, and lungs natural. Abdomen natural. On the outer side of the middle third of the right thigh there was a well-marked swelling which extended from 2 inches below the great trochanter to within 1 inch of the knee joint. The skin over the swelling was not red or discoloured, but on palpation it felt hotter than the skin of the opposite side. The swelling had fairly well-defined margins, was painful to touch, and fluctuated at its centre. The femur felt thickened and irregular in its middle third.

X ray examination of left femur showed on anterior aspect of middle third a localised bony swelling attached to the bone and tapering at both ends into its substance. Outline of shaft of femur natural. The appearance shown in the X ray photograph is indistinguishable from the condition described as traumatic myositis ossificans. Over the dorsum of the right foot the skin was reddened and inflamed, hot to touch, and rather painful, but there was not so much pain on manipulation as might be expected from the appearance of the part. There was no fluctuation. X ray examination of the foot showed a fracture of the shaft of the second metatarsal bone. The other bones of the foot appeared natural.

*Treatment.*—An operation was performed on Nov. 24th under chloroform. An incision was made into the swelling on outer side of left thigh and a considerable quantity of purulent matter evacuated. The swelling appeared to be a breaking down hæmatoma. The abscess was drained. Bacteriological examination of the pus showed presence of staphylococci.

*Progress and remarks.*—There are three conditions for diagnosis in this case: (1) Abscess of the thigh; (2) bony swelling of femur; and (3) spontaneous fracture of the

second metatarsal bone. With regard to the thigh condition the X ray appearance strongly suggests the condition known as traumatic myositis ossificans, but in the presence of an abscess it is difficult to exclude the possibility of chronic inflammation as the cause of the bony swelling; in other words, the condition may be a chronic pyæmic abscess with inflammatory thickening of the underlying bone.

The reason for the spontaneous fracture of the metatarsal bone does not appear clear unless the cause could be one of general debility and toxæmia associated with excessive absorption of septic material from the ears and teeth. The abscess of the thigh healed well. The fracture of the second metatarsal bone of the foot gave little trouble. It was treated by splints, rest, and massage. At the end of a month the patient could walk without pain.

*Periosteal Sarcoma of the Lower Third of the Right Thigh; Spontaneous Fracture; Amputation of the Thigh.*

CASE 5.—A. McI., a private, aged 19, was transferred to the Norfolk War Hospital on Jan. 20th, 1919, complaining of swelling of the right knee. The history of the present condition was as follows. The patient stated that he was quite well until May, 1918. He then noticed slight pain in his right knee, perhaps caused by a twist. It was not severe, but gradually got worse, although it did not cause him enough trouble to report sick before Oct. 2nd, 1918. He was passed through a field ambulance, a casualty clearing station, and a general hospital, the condition being then diagnosed on his field medical card as synovitis of the right knee. On Oct. 8th he was evacuated to England. Since October, in spite of treatment, the knee had gradually got worse. It had become more swollen and he had been unable to move it without pain, which had been especially severe at night, often keeping him awake for many hours. He had noticed that in spite of increasing swelling of the knee the muscles of the leg had become very wasted. He had lost weight rapidly; he had no cough.

*Condition on admission (20-1-19).*—The patient was a pale, ill-nourished youth; obviously in pain. Temp. 98°4; had occasionally been 99° at night during the last month. Pulse 80; respiration 20. Eyes: pupils equal, react to light and accommodation. Tongue clean; teeth fair, some caries. No scars at angle of mouth. Ears; no discharge. No enlarged lymphatic glands felt in neck or axilla. Chest wall poorly covered. Skin dry; little subcutaneous fat. Heart and lungs natural. Abdominal wall very thin, nothing abnormal discovered in abdomen. No enlarged or palpable iliac glands. Inguinal glands palpable, both not markedly enlarged.

*Local condition.*—The patient lay with the right knee flexed, unable to extend or move the joint without severe pain. There was marked swelling of right knee-joint, the swelling having the characteristic form of distension of the synovial cavity, except that the swelling was especially prominent on the inner side of the joint just above the internal condyle. The skin over the joint looked natural; no enlarged veins over the swelling. Marked wasting of muscles of thigh and calf. On palpation the skin over the joint felt hot, the joint being very tender to touch, so that any attempt at movement caused great pain. An irregular, ill-defined swelling could be felt over and above the internal condyle. The upper margin of the swelling could be palpated 1 inch above the condyle, but no lower margin could be palpated. The swelling did not fluctuate. The lower end of the femur felt enlarged and there was abnormal mobility to be made out. The situation of the bony points was natural; no riding of the patella. There was 1½ inches of wasting in the thigh and calf of right leg. The circumference of right knee-joint was 1½ inches greater than that of left. There was no loss of sensation and reflexes were natural. Wassermann reaction was negative.

X ray examination showed very extensive destruction of bone at the lower end of the femur. At one situation the destruction had been so great that the bone appeared to have been "eaten" through. There was no evidence of any new bone formation. Microscopic examination of a sector removed from the growth showed that the growth was a spindle-celled sarcoma.

*Treatment.*—Amputation of the thigh.

*Remarks.*—This case illustrates a not unusual mistake in diagnosis, the case being first diagnosed as synovitis of the knee. The importance of an X ray examination in all cases where there is any suspicion of disease of a joint cannot be over-estimated. It is probable that this case would have shown changes in the bone had an X ray been taken when the case was first seen. The second point of interest is the X ray appearance, the destruction of bone being very considerable and the appearance being not unlike that exhibited by a case of advanced necrosis.

## Clinical Notes :

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### THE EFFECTS OF EXPOSURE UPON THE TERMINALS OF HANDS AND FEET.

By F. JEEVES, L.R.C.P. & S. EDIN., L.R.F.P.S. GLASG.,  
CAPTAIN, R.A.M.C. (T.); MEDICAL OFFICER, H.M. HOSPITAL SHIP—;

AND

E. R. HUNT, M.D. CANTAB., M.R.C.P. LOND.,  
LIEUTENANT-COLONEL, R.A.M.C. (T.C.); CONSULTING PHYSICIAN TO THE  
NORTH RUSSIAN EXPEDITIONARY FORCE.

THE following case illustrates the different effects of exposure to (1) alternating extremes of temperature, (2) prolonged low temperature:—

Corporal W. B., aged 39, a monumental mason in civilian life, came out to North Russia on Oct. 1st, 1918. He had since been employed at the base. He gives a history of having been rejected for the Army in 1914—he believes on account of his teeth. He was in France from January, 1917, to October, 1917, where he was gassed, but did not suffer from trench-feet or frost-bite.

From Oct. 20th to Dec. 16th, 1918, he was employed in building stoves. As is customary among Russian masons, a mortar was used composed of clay and sand. The workmen use this with their hands instead of with a trowel, as in England, and they dip their hands at frequent intervals in extremely hot water to prevent the mortar sticking to them. He did the same. The weather was very cold, and his hands were consequently being exposed to extremes of heat and cold alternately. His feet, on the contrary, were constantly wet and cold, for he was unable to wear his Shackleton boots, and his ordinary boots were wet through, as he was frequently standing in water. He was wearing these wet boots for many hours daily. The first parts affected were

FIG. 1.—Shows increased bone formation in the fingers.

his hands and left great toe; then the other foot. They swelled up and "the nails seemed to spread." He had pains of a stinging character, worse when the hands and feet were getting warm again and after he had stopped moving about. The pain in his toes at night kept him awake.

He continued to work in spite of the pain until Dec. 16th, 1918, when he went sick on account of the severity of the pain in his left great toe. He states that he had little blisters at the bases of his finger-nails, but that his feet were not blistered, although distinctly blue. He was admitted to the hospital ship on Dec. 19th.

I (E. R. H.) saw him for the first time some three weeks later. He was then recovering and was able to be up and about the ward. The terminal phalanges of all his fingers, his thumbs, and the toes of both feet were much enlarged, presenting the appearance of clubbed fingers and toes seen in cases of congenital heart disease, though without the discolouration usual in this condition. Sensation to pin-prick was very much diminished over the terminal phalanges of his right thumb and forefinger and middle finger. The

level of diminished sensation extended down to the middle of the second phalanx of the right ring finger and to the joint between the first and second phalanges of the right little finger behind, and to the metacarpo-phalangeal joint of the same finger in front. The left hand was less affected, but sensation was diminished over all the terminal phalanges. A very similar distribution of impaired sensibility was present over the toes of both feet. The knee-jerks were normal, but plantar reflexes only just obtainable. His pupils reacted to light. The lungs were normal. The first sound at the apex of the heart was reduplicated.

FIG. 2.—Shows erosion of the terminal phalanges of the toes.

The excellent skiagrams, for which I am indebted to Captain H. J. Cotter, M.C., R.A.M.C., show an interesting condition of the bones of the terminal phalanges of both hands and feet. In the fingers these bones show increased bone formation, whereas the terminal phalanges of the toes are eroded.

These different conditions illustrate remarkably the effects of alternating extremes of temperature as compared with that of prolonged exposure to cold only. The distribution of the sensory changes point to injury of the nerve endings and not to any peripheral neuritis. There was nothing to suggest a functional origin. The similarity of the sensory changes in both hands and feet suggests that the bone changes were caused by direct action of the temperature on the blood-vessels, and not primarily by interference with vaso-motor action through the damage to nerve-endings.

North Russia.

#### A CASE OF KERATODERMIA BLENNORRHAGICA.

By S. C. DYKE, M.B., B.Ch. OXON., D.P.H. OXON.,  
ASSISTANT BACTERIOLOGIST, COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

As details have been published of comparatively few cases of keratoderma occurring in association with gonorrhoea, the following may be of interest:—

##### *The Case Described.*

Patient, a private in a Labour Company in France, who, throughout his illness denied having ever had any venereal disease, was taken ill with "pains in the joints" about the last week of April, 1918. On May 5th he was admitted to a C.C.S.; temperature was then 100.6° F. and the left knee was greatly swollen. A diagnosis of acute rheumatism was made. Salicylates were administered and 50 c.cm. of turbid fluid showing polymorphonuclear leucocytes was aspirated from the left knee. On May 23rd the notes record swelling of the joints of the right shoulder, wrist, and hand.

He was admitted to hospital in England at the beginning of June. The affected joints were all still swollen and tender, though not containing appreciable fluid. A soft systolic bruit was present at the apex which was in the fifth intercostal space, half inch internal to the vertical nipple line. Patient was weak and emaciated. There was still irregular pyrexia, up to about 100.5° F. at night. Salicylates gave no relief and were discontinued.

##### *Condition of the Patient's Feet.*

About the beginning of July the condition of the patient's feet began to attract attention. On admission the skin of the plantar surface was thick and calloused and showed a

tendency to come off in crusts. This is a state of affairs occasionally seen in men after they have been in bed some weeks, and no particular attention was paid to it until it was noticed that as the flakes separated they did not leave clean pink skin underneath; on the contrary, as the flakes of thickened epidermis came away new ones formed underneath them. This condition became rapidly aggravated until the whole plantar surface, the sides of the feet, and the dorsal surfaces of the ungual and, to a less degree, of the second phalanges were covered with a thick horny layer of desquamating epidermis. Cracks appeared in this

FIG. 1.—Feet before commencement of vaccine treatment.

desquamating layer, which was shed in fragments from the size of half-a-crown to a fine dust. As fast as the epidermis was thrown off further keratisation occurred in the underlying epithelium, which was later in its turn desquamated. The process went on underneath the nails, most of which in time separated and came away. Some traces of the same condition, in the shape of a branny desquamation around

FIG. 2.—Feet one month after commencement of vaccine treatment.

the finger-nails, occurred on the hands. The palms were not affected. No inflammatory reaction accompanied the process, which was almost painless.

On June 6th a little sugar was present in the urine; this was absent at the next examination a few days later and thereafter.

#### *Treatment with Gonorrhœal Vaccine.*

At the end of June the case came under my care. The association of an arthritis, not responding to salicylates, with hyperkeratosis aroused suspicions of gonorrhœa. On looking for it a scanty purulent urethral discharge was found, which on examination by the pathologist to the hospital, Major A. G. Gibson, R.A.M.C., was found to contain Gram-negative diplococci. Further investigation revealed similar cocci and prostatic threads in large quantities in the urine. The Wassermann reaction was negative.

On the strength of the pathological report a course of gonococcal vaccine was given from July 10th to August 10th. A start was made with a dose of 5 millions, the dose being worked up to 300 millions, and 850 millions being given in the course of the month. The improvement in the condition

of the feet was immediate and marked. After the first few doses the further keratisation beneath the already separating epidermis ceased, and at the end of the month most of the thickened skin had separated, leaving normal epidermis beneath. At the same time the pyrexia ceased. The joint condition, which, under radiant heat and massage, was improving before the commencement of the vaccine showed no marked change.

About the middle of August the patient was evacuated to an auxiliary hospital. His general health was then excellent. The condition of the skin was normal, but there were still considerable thickening and stiffness of the affected joints, particularly of those of the right hand. The urethral discharge had disappeared.

#### *Remarks.*

The points of interest in this case would seem to be:—

1. The association of the skin condition with what was evidently a very severe attack of gonorrhœal arthritis.
2. Its late appearance in the disease.
3. Its prompt disappearance under vaccine treatment.

Oxford.

### CRYPTOPODIA: AN UNDESCRIBED DISEASE.

By E. C. BOUSFIELD, L.R.C.P. LOND., M.R.C.S.,  
D.P.H. CAMB. & LOND.,

DIRECTOR, CAMBERWELL RESEARCH LABORATORIES; BACTERIOLOGIST  
CAMBERWELL AND HACKNEY.

THE remarkable case described below, unique, so far as I have been able to discover, came under my notice whilst taking a "busman's holiday" in charge of the practice of my friend, Dr. T. T. Brunyate, of Woodstock, by whose kind help I was able to get the patient to London for exhibition at a scientific meeting.

#### *History of the Case.*

The patient, a fresh-complexioned woman of 44, had never been out of the country. Enlargement of the feet was first noticed at the age of 15, coming on during the day and disappearing during sleep. In the following year it increased so much whilst she was in service that she sought advice as an out-patient at St. Bartholomew's Hospital, but attended once only, as she had to leave her situation. She appears

FIG. 1.—Dorsal aspect, showing the widely-separated hair follicles.

to have continued in service, though with increasing difficulty, until her twenty-fifth year, when she was attacked by rheumatoid arthritis, which left her hands crippled, and since then the feet have got steadily worse, so that for ten years she has not been able to walk.

The photographs which I took of her in the Woodstock Infirmary show the condition better than any description. At the first glance the suggestion is that of elephantiasis, but the fact that the toes are not involved in the tumour, and

the great separation of the hair-follicles, indicating distension, not hypertrophy, together with the translucency of the tumours, negative the idea of that disease.

The swelling extends from about three inches below the knees, and involves the whole of both legs and the dorsa of the feet, but stops absolutely short at the margins of the soles, or rather folds over about half an inch higher all

FIG. 2.—Plantar aspect, showing growth protruding between the toes.

round. Round each ankle there is a well-marked collar, with protuberances not coinciding with any anatomical structures. The skin pits deeply on pressure, but there is neither pain nor tenderness.

Heart, lungs, and kidneys are sound. A somewhat hasty blood count showed 32 per cent. polymorphonuclear leucocytes, 17 per cent. transitionals, 51 per cent. small lymphocytes, but neither large mononuclears nor eosinophiles. The red cells were very irregular in size, varying from 0.5 to 1.5 of the normal, but poikilocytes were few.

#### Remarks.

The condition of the blood seems to indicate profound myeloid or lymphatic changes, especially as there was marked leucopenia. No mechanical obstacle to the return flow of blood or lymph appears adequate to explain the peculiar features, the immunity of the feet for example. Numerous specimens of blood taken at night failed to show evidence of filaria. The only suggestion as to the nature of the case was that it might be a variant of Milroy's disease, but there is an entire absence of hereditary element.

*Note.*—Since the above was written my attention has been drawn by Colonel McAdam Eccles to a case which he published in the *St. Bartholomew's Hospital Journal* in April, 1906. He described it as a case of elephantiasis, and, as the toes appear to partake in the enlargement, this is probably correct, though I cannot pretend to decide in the absence of more exact details. My own case is now in the same hospital, under Dr. Morley Fletcher, and is improving greatly under thyroid treatment, though why it should be hard to say. The skin, as it contracts, is piling up into thick ridges, so that there has evidently been some hypertrophy.

De Crespigny Park, S.E.

**LITERARY INTELLIGENCE.**—Messrs. W. Heffer and Sons, Ltd., Cambridge, announce the early appearance of "Groundwork of Surgery for First Year Students," by Mr. Arthur Cooke. The book is intended for students just beginning clinical work in the wards or out-patient department.

**MR. WILLIAM LAUZUN BROWN.**—The death is announced of Mr. W. L. Brown, L.R.C.S. Edin., L.R.C.P. Glasg., who before qualifying as a medical man was attached to the editorial office of THE LANCET, first as a medical reporter and latterly as one of the sub-editors. He was a good shorthand writer and, having won a competition in stenography while a Scottish medical student, he attracted the attention of Sir William Gowers, at that time closely connected with the editorial staff of THE LANCET, and to Gowers Mr. Brown owed his start at this office. He did much useful work for THE LANCET for nearly five years, especially in taking charge of the reporting of various congresses and medical meetings. In 1894 he returned to Glasgow to complete his medical education, and on obtaining the Scottish diplomas went into general practice in London. He remained attached to journalism, and in papers and from platforms was the advocate of medical movements of various sorts. He was a member of the Finsbury Borough Council and Holborn Board of Guardians.

## Reviews and Notices of Books.

*Mortality Statistics of Insured Wage-earners and their Families in the United States and Canada.* By LOUIS I. DUBLIN, Ph.D., Statistician. With the collaboration of EDWIN W. KOPF, Assistant Statistician, and GEORGE H. VAN BUREN, Supervisor, Statistical Bureau. New York: Metropolitan Life Insurance Company. 1919. Pp. 397.

THIS publication presents the mortality statistics of the Industrial policy-holders of the Metropolitan Life Insurance Company for the six-year period 1911 to 1916, with a supplement for the year 1917. The statistics are essentially those of the wage-earning group of the population. In view of the circumstances and time covered, and the care exercised in gathering, editing, and tabulating the data, it is safe to say that these statistics constitute one of the best indices available of mortality and its causes among wage-earners and their families. Those working in mortality statistics, especially in connexion with life insurance, will find much to interest them. In order fully to appreciate the facts careful study is necessary, and many important matters are presented which are not to be found in works published in this country, such as the comparative mortality of the white and coloured races at the various age-periods. The comparative mortality from different diseases in the industrial population on the one hand, and in the general population on the other, forms an interesting study, and here the area covered by the data—it includes nearly all the states of the United States and the provinces of Canada—makes the investigation particularly valuable. The statistics, indeed, reflect the sanitary and social conditions prevailing throughout the industrial population of two great national units. The members of wage-earners' families are also accounted for in good measure, for a very large proportion of the total number of persons observed are the wives and children of wage workers.

The number of diseases dealt with is, of course, large, but attention may be usefully directed to certain maladies, such as tuberculosis, cancer, and syphilis, whose rates of incidence are especially interesting to official medicine. Taking first *pulmonary tuberculosis*, a total of 99,906 deaths is reported under this head, corresponding to a death-rate of 185.7 per 100,000 in the six years 1911 to 1916. A table is given showing the mortality from this disease, classified by colour, sex, and by age-period. The group of coloured persons in this experience displays a pulmonary tuberculosis death-rate at all ages between two and two and one-half times that of white persons. One interesting feature is the comparatively early age at which the maximum death-rate is found among the negroes—namely, between 20 and 24 years of age. Among white males the maximum is reached between 35 and 44 years, and among white females between 25 and 34 years. Further, the mortality from tuberculosis of the lungs among coloured males at the age-period 5 to 9 years is over ten times as great as among white males at that age. In discussing the comparative mortality from pulmonary tuberculosis among the industrial and general population respectively, it is shown that among insured white males, at all ages, the mortality is 31 per cent. higher than among all males of the general population. Females in the families of wage-earners showed an excess of only 13 per cent. Another point of interest brought out is that the children of wage-earners who reside in cities and are presumably more exposed to infection and to the hardships incident to their economic stratum, show no higher rates from pulmonary tuberculosis than children in the general population, of whom one-half reside in rural areas. Judging by the way in which children are housed in this country in country districts this experience is not so surprising as it appears at first sight.

Turning now to *cancer*, the statistics show that white males show emphatically higher cancer death-rates at every age period than were recorded for coloured males. Comparisons between the cancer death-rates of white and coloured females are practicable beginning with the age-period 25 to 34 years. Between 25 and 44 years the cancer death-rates of white females were decidedly lower than the rates for coloured females. Between 45 and 54 years the rates were practically the same. Beginning with the age-period 55 to 64

years and continuing to the highest age-period in the table, the cancer death-rates of white females were higher than the rates for coloured females.

In discussing the mortality from *syphilis* the authors remark that statistics are likely to be fallacious because of the tendency of medical men to conceal this disease in their reports of causes of death. But even the figures, defective as they are, serve to indicate some important relations (of syphilis mortality) in the several colour and sex classes. The death-rate among coloured lives is consistently higher than among whites. The rates are about 3 to 1. The rates are much higher for males than for females in each one of the colour groups.

The figures concerned with the mortality from other diseases are similarly considered, the whole work forming a valuable addition to our statistical knowledge of the causes of death in the varying conditions of race, age, and sex. The authors may be congratulated on the success of their endeavours in collecting and criticising an enormous mass of material, and the results will doubtless be received with the greatest interest by all concerned in the insurance world.

*Aids to Ophthalmology.* By N. BISHOP HARMAN, M.A., M.B. Cantab., F.R.C.S. Eng. Sixth edition. With 163 illustrations. 1919. London: Baillière, Tindall, and Cox. Pp. 226. 3s. 6d.

We can thoroughly recommend this little book to every student of ophthalmology. It is written in an easy, interesting style, and contains as much useful information in proportion to its size as any book we know. Moreover, it can be carried about in the pocket. The chapters on the external diseases of the eye include some elementary bacteriology of the conjunctiva. The different forms of cataract are clearly explained. The main facts about glaucoma are stated, while the controversies to which it has given rise are left on one side. The chapters on refraction and the fitting of glasses are practical and sufficient. When he comes to the ophthalmoscopic diagnosis of fundus disease the student will need to supplement what he finds here. There is, for instance, no mention of such a common disease as albuminuric retinitis. References are given, however, to ophthalmoscopic atlases, one of which would be found a most useful adjunct by the beginner.

The chapter on Ocular Therapeutics, while excellent so far as it goes, does not go very far. The advice, however, to use nitrate of silver in a solution of glycerine and to compare its action with that of the newer proprietary silver salts on patients who have both eyes affected with conjunctivitis is worth following. Of the additions in the sixth edition, compared with the fifth, we note a new chapter on Diseases of the Vitreous, and the inclusion in the final chapter on operations of a description of the author's reefing operation for the advancement of a muscle in cases of squint. This operation, in its originator's hands, has given good results and it does not entail the bandaging of both eyes and consequent confinement to the house or hospital; but it is a difficult one to perform. A chapter on Eye Conditions in School Children is of special value, embodying the author's experience of many years' work in connexion with the public elementary schools of London.

*Constipation and Allied Intestinal Disorders.* By ARTHUR F. HURST, M.A., M.D. Oxon., F.R.C.P., Physician and Neurologist to Guy's Hospital; formerly Consulting Physician, Salonica Army. Second edition. London: Henry Frowde, Hodder and Stoughton. 1919. Pp. 440. 16s.

The present volume, though described as a second edition of the book first published in 1909, is very largely a new publication. Much has been rewritten, and new chapters have been added on such subjects as methods of examination, intestinal adhesions, visceroptosis, stasis in the cæcum and ascending colon, and spa treatment. While the book presents the results of the author's own observations, it also embodies the more important facts relating to the subject to be found in the English, the American, the French, and the German literature. The subject-matter is divided into convenient sections. The first of these deals with the physiology of the intestinal movements and of defæcation, and includes an interesting account of "mass peristalsis,"

the term which is now usually employed to describe the movements of the colon. The next section deals with methods of examination. These include the usual physical examination; the giving of charcoal lozenges, by which device it is possible to estimate the total time taken in the passage of any particular meal through the alimentary canal; examination by X rays; the examination of faeces by physical, chemical, and bacteriological methods; and, finally, examination of the lower bowel by the sigmoidoscope. Section 3 treats of the causes of constipation: factors influencing the passage of intestinal contents along the colon are first considered and then the causes of "dyschezia" or defective defæcation are passed in review. The next section considers the symptoms of constipation in all their protean manifestations. Section 5 is concerned with treatment, and the importance of prophylaxis is duly emphasised. The majority of cases of constipation, as the author insistently teaches, can be cured without drugs if proper treatment is instituted at a sufficiently early stage. Indeed, in dyschezia purgatives are either absolutely useless or they only have an effect when fluid stools are produced, a considerable quantity of fluid and nutritive material being thereby wasted. Two further sections deal with the rather more special subjects of constipation in infants and in soldiers.

The book is illustrated by 56 figures, most of which are reproductions in black and white outline of bismuth meal investigations. It is seldom that the reader of medical monographs meets with an account of a subject so rationally set forth and in which the conclusions are so intimately based upon direct experiment and observation. The author is to be congratulated upon the scientific acumen which has shaped his labours.

*Heredity.* By J. ARTHUR THOMSON, M.A., LL.D., Professor of Natural History in the University of Aberdeen. Third edition. London: John Murray. 1919. Pp. 627. 15s.

A THIRD edition has just appeared of this valuable manual, published originally 12 years ago. During that time it has served, as it was intended to do, as an introduction to the study of heredity, and the fascinating interest of the subject and its great practical importance have been proved by the success of the manual. Professor Thomson has furnished a book which illustrates for the benefit of those who are not experts in biology the main views which are held in this sphere. He defines the terms in common employment, and discusses the accepted theories as to the physical basis of inheritance, showing how the tendency to breed true is subject to variations, fluctuations, and mutations. Disputed questions like telegony and the transmission of acquired characteristics are dealt with in comprehensible language; a long chapter on heredity in disease may be commended to all our readers, and the same may be said for the exposition of Mendelian law. The whole book is, as we have said before in much the same terms, fascinating and instructive, while apt illustrations and a full index add to its value.

*Manual of Anatomy, Systematic and Practical, including Embryology.* Originally written by the late A. M. BUCHANAN, M.A., M.D., C.M., F.R.F.P.S. Glasg. Fourth edition. With 677 illustrations. London: Baillière, Tindall, and Cox. 1919. Pp. xii. + 1743. 30s.

THE general arrangement of this edition remains as in the last, and the old terminology is still adhered to. The book is now in the hands of a committee of London anatomists, who have made only a few alterations in the text, and are clearly waiting for an increase in their number before dealing at all drastically with the revision of the whole work.

*Studies on Acari. No. 1, the Genus Demodex, Owen.* By STANLEY HIRST. London: Longmans, Green, and Co. 1919. Pp. 44 + xiii. 10s.

Mr. Hirst has carried out a very painstaking research into the distribution and morphology of the genus *Demodex*, and has discovered the parasite in certain mammals in which until now it has not been known to occur. His descriptions are careful and clear, and are admirably illustrated in 13 plates and four text-figures.

# FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of

Professor CHARLES ACHARD,  
PROFESSOR OF PATHOLOGY AND THERAPEUTICS IN THE  
UNIVERSITY OF PARIS.

AND

Dr. CHARLES FLANDIN, D.S.O.,  
CHEF DE CLINIQUE À LA FACULTÉ DE PARIS.

## RADIOLOGICAL EXAMINATION OF PSEUD- ARTHROSES BEFORE AND AFTER OPERATIONS OF BONY GRAFTS.

By PAUL AUBOURG,

PROFESSOR AGREGÉ, CUNEO'S LABORATORY FOR RADIOLOGY.  
(Centre for Surgery of Bones, Hospital 75, Cannes.)

JUDGING from the reports of the last French Surgical Congress (Paris, Oct. 4th, 1918), the treatment of pseudarthroses is at present very much to the front. In this highly complex question of the reparation of pseudarthroses radiology can give the surgeon valuable indications—*before intervention*, in order to get an idea of the structure of the bony extremities, of their morphology, and of their mutual relationship; *after intervention*, in order to get an idea of the evolution of the graft, of the bony reparation of the extremities, and, above all, of secondary deviations which could invalidate the primary and immediate results of the operation.

Surgeons know how great the number of pseudarthroses is at present, and how much greater it will be by the huge number of wounded who now decline, but will demand intervention later. Our colleagues at the demobilisation centres estimate the number of wounded now declining any intervention in the case of pseudarthrosis as 8 out of 10. But if it is difficult to ascertain even approximately the number of wounded who will have to be sent to hospital and operated upon later on, one can at least compute the percentage of lesions in the case of wounded sent to the Centre for Surgery of Bones at Cannes. In a first series of 161 wounded, six humeri, five forearms, and four tibias are found to one femur. I would remind my readers that this centre was formed a year ago at the request of my teacher and friend B. Cuneo, *professeur agrégé* in the Medical Faculty of Paris, in order to study, experimentally on animals and clinically on men, the development of grafts in pseudarthroses, the losses of bony substances, and serious lesions in articulation.

### *The Surgeon and the Radiologist.*

Radiology plays such an important part in the study of pseudarthroses that one can say without exaggeration that there are few branches of surgery, recent fractures included, in which the close, constant, coördinated and methodical coöperation of the surgeon and the radiologist is more strictly demanded. To discuss the radiological side of pseudarthroses would therefore be equivalent to going to the bottom of the study of these lesions. Now, at the present time this is not possible, for "not a single chapter of this study can be looked upon as definitely closed" (B. Cuneo). Consequently the present article has no other aim than to show which are the problems set the radiologist by the surgeon and the way in which the former must strive to solve them.

It seems fairly difficult, from the radiological as well as from the clinical point of view, to give a precise definition of pseudarthroses. According to Pl. Mauclair there is a *pseudarthrosis* when the deviation between the fragments does not exceed 3 cm.; there is *loss of substance* properly so called when there is more than 3 cm. deviation between the bony extremities. The first conception that must be gained in the case of pseudarthrosis is the conception of non-consolidation. Radiological diagnosis between simple retardation of consolidation and definite absence of consolidation is often impossible; it is therefore advisable to perform successive examinations, say one each month. If at the end of several months the extremities of the bones not only do not present any apparent growth, but even seem to be decalcifying and becoming atonic, it is possible, in view of this retrograde process, to discuss the possibility of definite non-consolidation. Moreover, it is well to dis-

tinguish *pseudo-losses of substance* by lengthening of the limb amongst *true pseudarthroses* when the bones are in contact from *true losses of substance*; they are easily reducible and have only been ascertained in the case of the humerus.

### *The Types of Pseudarthrosis.*

From the radiological point of view two principal types of pseudarthroses may be distinguished. According to the aspect of the bony extremities, they may be classified into: (1) pseudarthroses where the more or less fine bony extremities, sometimes lanceolate, sometimes regularly transversal, do not present any growth, whether they are in contact or at a distance from each other; (2) pseudarthroses where the bony extremities on the contrary present bony proliferations recalling articular extremities and presenting at first sight a more or less perfect (Obs. 232) and more or less close pseudo-articulation.

Sometimes, when there is a deviation between the two fragments, one may find, when very soft rays are used, traces on the plate of an opaque trail which might be remains of superiosteal resection for removal of splinters (Obs. 320), for in the huge majority of wounded where the fractured bones have not united splinters have been freely removed, mostly within 48 hours of being wounded. Sometimes the intervention occurs of a fibrous or osteofibrous callus between the two fragments, not sufficiently thick to appear as a shadow projected on the radiograph. This fibrous, invisible callus of slight density may in time and under certain circumstances become progressively ossified; it may be considered as intermediary between a very soft fibrous callus which allows of a certain mobility of the diaphysis, and a bony callus which in time becomes a vicious callus in consequence of secondary deformations at the point of fracture or resection. In fine, all intermediary states between pseudarthrosis in which the fine extremities are not joined by any visible tissue and badly set fractures are found with a more or less soft fibrous tissue or, on the other hand, more or less ossified. In these circumstances it seems impossible to attribute any radiological pathognomonic character to pseudarthroses.

As a result of radiological examinations the arrest of ossification has been noted several times and seems more established. Such a bony extremity which seemed to be putting forth growth halts in its expansion in the articular type; another ends in a transversal shaft or in an oblique spire without proliferation. One would think that the two bones were struck into sterility, with impossibility of forming any conjunction. This phase betrays itself very often on the plates by the closing of the medullary canal, as in amputations. From the radiological point of view it is important to study the medullary canal throughout all its length. One sometimes finds several centimetres from the pseudarthrosis spots where the medullary canal seems closed a second time, as in certain cases of infantile osteomyelitis. (Obs. 46.) In general the bony tissue is less thick and more transparent than usual; it is decalcified. But it is to be borne in mind that even with a normal radiological appearance the bone may be found very pliant, "like cardboard," at the moment of intervention, or actual operative interference. (Obs. 283.)

On the other hand, under a linear aspect, a bone may appear not joined, and another bone may appear to be growing and joined on the plates, whilst intervention shows the contrary. (Obs. 333.) In a case of double pseudarthrosis of the forearm, the radius, which on the radiograph appeared consolidated, proved on intervention to be mobile in a pseudarthrosis of the close type; whilst the ulna, which appeared in linear aspect on the radiograph to be without growth, was found to be quite solid.

Many wounded men have come to the prosthesis centre with osseous fistulas; the radiograph has made it possible to recognise the *splinters*—but without giving assurance whether they were adherent or not—and above all the *sequestra* with their characteristic bell-like shape, bony islets

surrounded by a clear zone. (Obs. 13.) The X rays have permitted the observation of the results of preliminary operations for osteitis, performed before the actual operation of bone-grafting.

#### *Radiological Study of the Deformations and their Reduction.*

Some writers have thought that the decalcification or osteoporosis of the extremities in cases of pseudarthrosis might be due to a lesion of the artery nourishing the bone. Examination of the plates enables us to invalidate this opinion, which Pl. Mauclore had already placed in doubt. Contrary to the opinion of M. Chutro, the best argument lies in the verification of osteoporosis and decalcification at a distance, outside the bone attacked by pseudarthrosis. Observation 71 is typical: there exists a decalcification of the radius, but also of the carpus and metacarpus as marked as of the radius, recalling the appearance of certain tuberculous "rheumatisms." It is certain that lesion of the artery nourishing the radius cannot be made responsible for these lesions. Perhaps the ligatures of the great trunk arteries of the limbs are more important.

The X rays give us information about some certainly rare results of the forms of treatment given to the wounded

determine the frontal and lateral correspondences on which the graft is to be made.

It may be laid down as a rule that in all cases where a bone has suffered loss of substance there is produced automatically a frontal deformation and often a deviation from the axis on the part of one or both fragments. It is most important to investigate these deformations in order to correct them as far as possible before intervention. We have here an indication not to put off intervention too long in the case of wounded men; the deformations are the more marked and difficult to reduce the older the cases are. Experience shows that this reduction of deformity cannot always be made at the moment of intervention, even with the powerful forceps of the Heitz-Boyer or B. Cuneo types. As a matter of fact, the deformities would inevitably have a tendency to reproduce themselves, after reduction, accompanied by much loss of blood, under anaesthetics. On the contrary, the facts show that the reduction of bony deformations before operation in pseudarthroses must be slow, gentle, with continuous progressive traction. The devices invented by P. Rolland, head of the laboratory of the Centre for Osseous Prosthesis at Cannes, are based on this idea. But if the general principles are

FIG. 1.—Deviation of the inferior segment of the radius in consequence of a loss of substance of 10 cm.

FIG. 2.—Progressive reduction of the displacement of the inferior fragment of the radius in Fig. 1 with the aid of a corrective appliance with screws applied to the ulnar side and over the metacarpal bones.

FIG. 3.—Pseudarthrosis of the ulna. The plate shows the deviation of the superior fragment of the ulna towards the radial diaphysis. There is a separation between the radial cupule and the humeral condyle, and there is also a subluxation outwards of the radial cupule.

before their admission to the centre for bony grafts: *Very prolonged immobilisation* or *simple removal of morbid parts*, with the same hopeless state of sterility of the bony extremities, verified by radiography for several months in succession; *bone sutures after suoh removals* with wires which end either by breaking or by sawing through the bony extremities which they are intended to keep in contact (Obs. 18); *application of metallo plates*, which sometimes produce, on the side opposed to the plate, proliferous osteitis, often of great size (Obs. 500), presenting the appearance of an inflammatory type of osteitis; *application of clasps*, which in spite of their perfect application have not been able to bring about (Obs. 285) any bony proliferation of the extremities; *pegging with ivory or segments of the fibula*, in spite of which the mobility has persisted. (Obs. 320.)

Far more important than the information given as to the structural state is the radiological study of the *deformations of the bone before operation*. Examination by X rays is here of capital importance. Clinical examination alone cannot

uniform, the application is and must be particular to each case, after examination of the plates. And so X rays are wanted first of all to ascertain the deformations in such a way as to give instructions for constructing the apparatus, then in order to judge of the successive advances of the reduction, and lastly in order to decide on intervention when the maximum reduction has been attained.

#### *Prevalent Deformities of Particular Limbs.*

It is interesting to note for each limb the deformations most usually ascertained on the plates.

*Forearm.*—Pseudarthroses of the radius, especially in its middle part, without and still more with loss of substance amounting even to several centimetres, produce a deformation which may be called characteristic. (Obs. 71.) Viewed from the front the inferior radial fragment has a marked inward deviation, and its superior extremity places itself before or behind the ulna. This deformation is sometimes so great that it can be felt on the ulnar edge of the forearm.

(Fig. 1.) There follows an ascension of the radial styloid which, instead of being below the ulnar styloid, reaches the same or even a higher level; there is a projection outwards from the carpal group. Viewed laterally, it sometimes shows on the plate exactly like the back of a fork on the posterior or anterior face of the forearm. However marked these deviations may appear on the radiograph, they are generally reducible by means of the apparatus of P. Rolland. (Fig. 2.) As for the superior fragment of the radius, it is in general less inclined towards the ulna; it is often found in light flexion, and most often in rotation; on the whole, a radius is found in pronation as regards its inferior fragment and in supination as regards the superior fragment. From the radiological point of view it is difficult to estimate the amount of supination of the superior fragment; it is therefore advisable in such cases to take plates of the limb on the healthy side in absolutely pronate and supine positions as well as in intermediate positions, in order to judge by comparison, relying above all on the bicipital tuberosity. (Obs. 407.)

Losses of substance of the ulna may bring about a falling back of the superior humeral fragment, together with a raising of the inferior fragment on the anterior face of the forearm. (Obs. 246.) Laterally there may exist a deviation of the two fragments of the ulna towards the radius, forming the shape of a capital K. (Obs. 401.)

But whether the radius or the ulna be involved, it is important to recognise one fact which is marked at the outset and only accentuated in the sequel—viz., the incurvation of the healthy bone in isolated pseudarthroses of the forearm. Radius curvus is extremely frequent in pseudarthroses of the ulna, and ulna curva in pseudarthroses of the radius. They may be observed even with a minimum loss of substance. (Obs. 317.) The incurvation may be axial, causing the interosseous space to disappear (Obs. 16), or peripheral. In the course of intervention any attempt at reduction is most difficult, if not impossible. Obs. 36 is characteristic on this point:

"Wounded man presenting pseudarthrosis with inward deviation of the radius, in contact with the ulna. After resection of the fragments it is impossible, in spite of all efforts, in the course of the intervention to put the two fragments in direct prolongation of each other."

It must be added that an incurved radius or ulna has a quite natural tendency to become exaggerated in the sequel. Consequently B. Cuneo does not fail to draw attention in the discharge papers of wounded men who have declined intervention to the possible aggravation of the ulterior functional prognosis.

Both in simple pseudarthroses and in double pseudarthroses (Obs. 15, 30) one can observe radio-ulnar synostoses. Always more marked, more extensive, and more dense at the time of intervention than appears on examination of the radiological plates, these synostoses are in themselves causes of super-added deviations.

With all these deformations, exaggerations of pronation and supination, incurvations and synostoses, reactions on the adjoining articulations are naturally expected. With regard to the articulation of the wrist all degrees of subluxation may be found; external subluxation pushing the cuneiform and the pisiform within the axis of the ulna and causing the ulnar styloid to rise beneath the skin (Obs. 264)—internal subluxation with the scaphoid and semilunar separated from their facets at the inferior extremity of the radius. (Obs. 100.) With regard to the articulation of the elbow, an external radio-humeral subluxation can be verified. (Obs. 15, 84.) (Fig. 3.) The older the pseudarthroses involved, the more frequent and marked are the subluxations.

*Upper arm.*—Solutions of continuity of the humerus have as corollary a forward flexion of the inferior fragment on the fold of the elbow; the flexion may exceed 45°. (Obs. 66.) This swing of the inferior fragment is also accompanied by an inward or outward twist. It is useful to know this fact in order to interpret the plates, which on a first examination would give the impression of a lesion of the elbow, whilst it is really a matter of a faulty position. On the other hand, it is hard or even impossible to correct this faulty position at the time of taking the radiograph, for this torsion is sometimes accompanied by an ankylosis (at least functional) of the elbow; the olecranon then appears hidden by the epicondyle or the epitrochlea, whilst it ought to appear clearly disengaged below the condyle or the cochlea.

(Obs. 31.) This deformation is common in pseudarthroses of the middle third, but especially so in those of the inferior third; it is then often combined with a twist or deviation from the axis of the superior fragment. As to abduction of the superior fragment, it has been verified particularly in pseudarthroses of the superior third.

*Thigh.*—Two deviations are particularly met with in pseudarthroses of the femur: *abduction of the superior fragment and backward lapse of the inferior fragment.* (Fig. 4.) The abduction takes place in pseudarthroses situated high up (Obs. 135) or pseudarthroses of the lower third. (Obs. 59.) It is progressive and very difficult of reduction, either under chloroform or by means of corrective apparatus before operation. The same is true of the lower fragment; its reduction is very difficult in pre-operative stage.

*Leg.*—The deformations of the leg recall the usual deformations in fractures: flexion and backward swing of the fragments. Sometimes there is conjoined with it either an attraction of the tibia towards the fibula forming the picture of a capital K, or, on the contrary, a lozenge-shaped separation. But it is above all important to examine the articular modifications at the level of the knee and the instep. At the knee there may exist either an internal subluxation (Obs. 88), or a marked separation between the external condyle and the external tibial plateau (Obs. 126). At the instep there may be an outward lapse of the astragalus; with regard to the fibula, the tibio-fibular diastasis must be investigated.

#### *The Responsibility of the Radiologist Before and After Intervention.*

Such are the bone deformations which may be met with in pseudarthroses before intervention. From the point of view of radiological technique there follows for the radiologist the indication to take a plate of the whole bone segment (diaphysis and epiphyses) and of the nearest articulations. It is very frequently useful to take a plate of all the opposite healthy bone segment in order to judge of the often very small differences in the articular relations. Moreover, the radiologist must strive to place the limb to be radiographed in the most favourable anatomical position. Where this is impossible *stereoscopic radiography* is useful to allow of estimating the relationships of the two fragments to each other and the mutual obliquity of their separation. Finally, in the case of lengthening or shortening of the limb *radioscopic examination* can be useful before intervention, in order to mark on the skin the point corresponding to the pseudarthrosis, so as to permit the surgeon to centralise his incision. In general all plates (from 30/40 to 13/18) are reduced to glass positives 9.12. They are more easy to read as a series, especially with a strong magnifying glass. Stereoscopic plates are reduced to glass positives 45/107, so as to be examined as a series in a Richard's taxiphot.

According to the practice of B. Cuneo intervention consists in taking an inlay from the tibia, of such length and breadth that it can be fixed in the two grooves cut in the superior and inferior fragments of the bone to be grafted. P. Rolland's apparatus made by the firm of Barriquand and Marre, a first model of which has been presented to the Surgical Society by B. Cuneo,<sup>1</sup> allows with the greatest precision of cutting mortises and inlays from an inlay of 21 cm. in length by 15 mm. in breadth placed on a tibia (Obs. 293), to an inlay 3 cm. long and 3 mm. broad placed on a phalanx. (Obs. 319.) The fixation of the inlay in the mortises is performed by means of metallic cables of soft galvanised steel either round the bone or through the bone by means of drilling. In order to be immobilised as rigorously as possible the limb is finally placed either in P. Rolland's appliances of moulded leather or in plaster appliances.

B. Cuneo teaches that in order to obtain a good result there must be intimate contact between the faces of the inlay and the mortises, so as to establish reciprocal penetration of the vessels of the recipient bone into the inlay. But above all things this contact must be very prolonged (nearly a year) and remain as perfectly intimate as possible. Now, after intervention, as the result of hæmatoma or of suppuration in the first days, after cicatrisation following on muscular atrophy in the following months, the volume of the member placed in the containing appliance may vary as

<sup>1</sup> B. Cuneo: Soc. de Chir., June 25th, 1918.

FIG. 4.—Pseudarthrosis of the femur. The superior fragment is in abduction, the inferior in adduction.

FIG. 5.—Osteoperiosteal graft of the radius performed without previous correction. The plate shows the disappearance of the inter-radial interosseous space. There is also an ascension of the radial styloid apophysis.

FIG. 6.—Pseudarthrosis of the tibia. Bony graft performed without reduction before intervention. After intervention, in which the reduction was only temporary, progressive post-operative deformation.

2 to 1. Radiological examination is indispensable to know whether the graft has remained in its proper place and in proper contact with the bony extremities. It is advisable to watch it by repeated examinations; the radiograph only allows us to know whether the inlay has really remained in contact. If there is any slight displacement the plates show us in which direction it must be reduced when bringing a fresh appliance into use. Radiological examination is all the more important in the consequences of operations for pseudarthrosis, as two factors may displace the inlay during the phase of cicatrisation—firstly, the prolonged presence of the wires sustaining the inlay; secondly, the tendency of the fragments of the bone to reproduce progressively the same deformations which we have noticed above in the examination of the bone before operation. With regard to the metal wires which sustain the inlay, radiography shows us two evolutions of the holes drilled at the time of intervention in order to pass the wires. The hole may either remain the same in size as when first drilled, or it may become enlarged in the proportion of 1 to 3. (Obs. 66.) It is clear that in these conditions of enlargements of the holes, due either to a very slow sawing action of the bone, or perhaps to electrolytic phenomena, the imperfect immobilisation of the inlay as revealed by the plates must be removed by corrective appliances. As to secondary deformations, it cannot be repeated too often that limbs affected with pseudarthrosis, even when reduced before intervention, have a tendency to reproduce the ante-operation deformations after intervention. (Figs. 5 and 6.) The same muscular, tendinous, and even cutaneous causes produce the identical results after intervention. It is desirable to watch the deviations in the containing appliances, and even sometimes to apply corrective appliances with continuous, very slow and gentle extension, just as in the attempts at straightening and correction before the operation.

#### The Technique of Intervention.

The inlay must be maintained in its proper place, directly by metallic wires operating at the point of contact, indirectly by retaining and reducing appliances which operate chiefly to hinder secondary deviations of the bone fragments and to avoid partial or total luxations of the inlay outside of the mortises. Numerous facts have shown the value of this intimate and necessary contact—e.g., the following observation (Obs. 29)—which has all the value of a real experience:—

“Wounded man presenting a fracture of the second metacarpal necessitating excision of four-fifths of the second metacarpal. In spite of subperiosteal ablation no bony regeneration. A third metatarsal was grafted in place of

the wanting metacarpal. Intervention took place on account of the non-regeneration and especially of the functional trouble of the index which placed itself faultily under the medius in flexion. Eight months afterwards a radiograph taken from the front shows that the head of the grafted metatarsal, which had at first retained its normal original configuration and structural aspect, has now become completely *atrophied*, has disappeared as to its external radial half and become rarefied and decalcified as to its internal ulnar half. But above all the radiograph of the profile

FIG. 7.—Inlay placed on a long loss of substance of the radius after reduction of the inferior fragment before intervention. (Comp. Fig. 2.) As a precaution the reducing apparatus has been left in place after intervention to prevent secondary displacements.

FIG. 8.—Evolution of a graft of 16 cm. placed on a loss of substance of the radius. The inlay is being sheathed progressively by the bony tissue which seems to start from the extremities of the bones on which the inlay has been grafted.

shows that the segment of the metatarsal, resting in a small groove at the base of the metacarpal, is now shifted; the grafted metatarsal is now displaced forwards and outwards in the palm, losing all contact with the stump of the metacarpal.

A second intervention consisted in placing the two bones in contact by means of a metal wire. Successive radiographs have shown that the head of the metatarsal has not only ceased its regressive process, but has also become markedly recalcified."

In this case radiography has shown that a grafted bone atrophies when it has lost its vasculo-nervous contacts with the receiving bone of the graft. But provided that the contacts are re-established, there is not only an arrest of atrophy, but there is also a marked tendency to reparation and recalcification.

As to the inlay, it follows that if the inlay dislocates itself entirely and slips out of the mortises its work on the bony extremities completely ceases. The fact is proved still better in the case when the inlay is dislocated at one of its ends and remains in osseous contact at the other. The first remains sterile and makes a new pseudarthrosis; the second continues in osseous proliferation on the good path of bony reparation of the extremity with which it has remained in contact. (Obs. 18, arm; Obs. 10, leg.) These dislocations are the more important, as they may be accompanied by fracture of the inlay (Obs. 19) at the time when the inlay is passing through a period of atrophy, regression, or softening. Further, to study the typical method of reparation of the extremities of the bone and the evolution of the inlay it is advisable to examine the plates of a case where the inlay has retained intimate contact with the mortises, without secondary deviations of the bony segments, throughout several months. (Fig. 7.) The diagram, issued by B. Cuneo to the Society for Surgery, of the evolution of a graft for loss of substance of the ulna is characteristic. In the first month one may not see any perceptible structural modification on the plates, but in the second or third month one sees two kinds of modification of the inlay. Its two bony extremities in contact with the mortises seem to be lightly atrophied, or, more precisely, appear to be becoming a little decalcified, whilst the middle part of the inlay seems to undergo hypertrophy. It must be noted that the atrophy of the extremities and the hypertrophy of the middle part occupy the medullary zone of the inlay; on the other hand, the cortical subperiosteal zone of the inlay does not undergo any modifications at this time.

At the level of the bony extremities the bones which have been cut transversely appear in the second and third month to be budding out in conical shape towards the inlay, especially on its medullary face, as if to sheathe the inlay. (Fig. 8.) It follows that the intersegmentary zone diminishes; it is easy to measure on the plates (taken at the same distance) the distance between the segments of the bone during the subsequent days and months. This distance diminishes progressively, especially in the fourth month. Later on the two bony cones come into contact, and the inlay appears like a prop which the two extremities of the bone sheathe completely. Even after a year (Obs. 18) it is easy to trace the inlay on the plates, perhaps somewhat modified as regards density and volume, in the midst of the new bony growth of the extremities.

As regards the subperiosteal cortical face of the inlay, one sees a kind of atrophy from the fourth to the sixth month, revealing itself on the plate by a wavy line which contrasts with the linear straightness of this vertical face immediately after intervention. This atrophy usually appears in the centre part of the inlay. If this atrophy is exaggerated, either as the result of too prolonged suppuration (Obs. 246) or of a loss of contact which suppresses vascularisation by tearing the newly formed vessels (Obs. 84), necrosis in the first case and reabsorption in the second may produce a sequestrum, usually lamellar, which is isolated and is very easy to remove secondarily. If these lesions reach a greater degree one can see on the plates such a loss of substance and such a degree of atrophy that the inlay may present a veritable spontaneous fracture. Finally, the entire loss of contact or exaggerated suppuration may end in either complete atrophy of the inlay and its disappearance, or in a state of free foreign body, necessitating excision. (Obs. 167.) It is possible that even with the inlay removed the bony extremities may continue to grow, as if by some osteotropic power (Imbert); the inlay has, by its temporary presence, given some proliferative power to replace sterility.

There remains the reparation of the tibia from which the inlay has been taken. Radiographic series show that the closing up of the bone is radiologically finished between the third and sixth month; by means of palpation it can often be established clinically in advance of radiology.

#### *In Conclusion.*

Such is in brief the information which radiology can give in pseudarthroses and their treatment by bony grafts. But in spite of the precision of the structural details and the knowledge about the deviations before intervention, in spite of the information furnished about the evolution of the graft and the reparation of the extremities of the bone, it is necessary to be quite clear that it does not do to ask more from the X rays than they can supply. Radiology may reveal many details, but it cannot reveal them all; once more it is only the complement of clinical observation. With these reservations it must also be borne in mind that in order to obtain the maximum of precision the plates must be examined long and often; they must be compared with each other and with cases already operated upon; in a word, a reasoned diagnosis of a radiograph must be made, bearing in mind the causes of error, deformations of the plates and superadded invisible elements. Understood in this way radiology seems to be a valuable auxiliary in the surgical treatment of pseudarthroses. As such B. Cuneo has studied it with all the authority which attaches to his work.

The French Supplement to THE LANCET—under the Editorial Direction of Professor Charles Achard, Professor of Pathology and Therapeutics in the University of Paris; and Dr. Charles Flandin, D.S.O., Médecin-Major de 2me Classe, Chef de Clinique à la Faculté de Paris—has appeared on the dates given in the following list, which sets out the titles and authors of the contributions:—

Sept. 21st, 1918: (1) The Microbic Diversity of the Enteric Fevers, by Professor Achard. (2) Post-Typhoid Atony of the Cæcum, by Maurice Loeper, Professor of the Faculty of Medicine and Physician to the Paris Hospitals.

Oct. 19th, 1918: (1) What the War has Taught Us about Tetanus, by Louis Bazy. (2) Tetanus Consecutive to Superficial Wounds and to Trench Foot: Treatment and Prevention, by Professor Raymond, Médecin Principal de 2me Classe.

Nov. 30th, 1918: (1) General Review of French Cardio-Pathology during the War, by Ch. Lanby, Physician to the Paris Hospitals, Médecin Major de 2me Classe. (2) Methods of Estimating Augmentation in Depth of Volume of Left Ventricle, by Dr. Bordet, Director of the Radiological Laboratory of the Centre of Cardiology of Professor Vaquez, Hôpital St. Antoine.

Jan. 11th, 1919: (1) Gunshot Concussion of the Spinal Cord, by Henri Claude, Professor in the Paris Faculty of Medicine, Physician to the Paris Hospitals; and Jean Lhermitte, formerly Chef de Clinique in the Paris Faculty of Medicine. (2) Contribution to the Study of the Manifestations of Emotional Shock on the Battlefield, by Cl. Vincent, Physician to the Paris Hospitals, formerly Medical Officer to the 46th and 98th R.I. and to the 44th B.C.P.

March 1st, 1919: The Surgical Complications following Exanthematic Typhus, by Dr. Paul Monre and Dr. Etienne Sorrel, Prosecutors to the Faculty of Medicine, Paris, Médecins Aide-Majors de 1re Classe, Surgeons to the French Hospital at Jassy.

April 5th, 1919: (1) Nervous Complications of Exanthematic Typhus, by A. Devaux, formerly Interne of the Paris Hospitals, Médecin-Major de 2me Classe. (2) Note on the Epidemic Diseases Observed in Rumania during the Campaign of 1916-17, by Dr. Henri Vnilet, late Interne of the Paris Hospitals.

May 3rd, 1919: (1) Malaria During the War, by G. Paiseau, Médecin-Major de 2me Classe. (2) Distribution of Soldiers, Temporarily Unfit through Malaria, in Agricultural Colonies, by Professor E. Jeanselme. (3) Studies on Renal Function in Chronic Nephritis, thesis by Pasteur Vallery-Radot, reviewed by Professor Charles Achard.

June 21st, 1919: (1) Recent Work on Cerebro-spinal Fever, by C. Dopter, Professor, Val-de-Grâce, Médecin-Chef to an Infantry Division. (2) Meningococcal Rheumatism and Arthritis, by Dr. Paul Sainton, Physician to the Paris Hospitals.

THE LANCET can be ordered through any Library in France, or through the following special agents:—

PARIS.—MASSON ET CIE, 120, Boulevard St. Germain.

EMILE BOUGAULT, 48, Rue des Ecoles.

CH. BOULANGÉ, 14, Rue de l'ancienne Comédie.

FELIX ALCAN, 108, Boulevard St. Germain.

M. CHOISNET, 30, Rue des St. Pères.

H. LE SOUDIER, 174, Boulevard St. Germain.

MALOINE ET FILS, 27, Rue de l'Ecole de Médecine.

VIGOT FRÈRES, 23, Rue de l'Ecole de Médecine.

MARSEILLES.—TACUSSEL AND LOMBARD, 54, Rue Paradis.

TOULOUSE.—EDOUARD PRIVAT, 14, Rue des Arts.

LONDON: SATURDAY, AUGUST 23, 1919.

## Small-Pox on the Continent.

THE recent increased incidence of small-pox on the continent of Europe is likely to give rise to some uneasiness among those who are acquainted with the comparatively unprotected state of a large section of our population against the onset of this dangerous and infectious disease. The present circumstances, as we have on previous occasions pointed out, are entirely favourable to the spread of small-pox to our shores. Hundreds of thousands of soldiers are returning from the various war zones, in some of which small-pox has lately been occurring, and the pent-up trade and shipping, so long restrained by the war, are now being let loose and bringing many passenger ships and cargo boats to British ports from the Mediterranean littoral, the Baltic, and the Black Sea, in all of which regions small-pox was recently, or still is, occurring in epidemic form. A brief outline of the incidence of small-pox on the continent during the first half of the present year, so far, at least, as information is available, may help the reader to gauge the extent of the danger already threatening this country—a danger which in the late autumn may, in our opinion, become still more acute and menacing.

Up to the middle of June 2586 small-pox cases had been notified in Germany, of which 734 were referred to the city of Dresden, which lies not very far from the borders of Austria. The disease has also been occurring at several ports along the German shores of the Baltic, including Danzig, Stettin, Swinemünde, and Königsberg. In the interior outbreaks were reported in several cities, among which were Berlin, Baden-Baden, Aachen, Leipzig, Frankfurt, and Hanover. At the last-named town the outbreak began in a camp in which Russian prisoners of war were interned. Previous to the war Germany occupied a high position as regards its vaccination and revaccination, and its resulting comparative immunity from the ravages of small-pox, notwithstanding frequent importations of the infection from Russia and Austria. The withdrawal for war service of many medical practitioners in Germany from practice and from public appointments, including that of public vaccinator, no doubt served to upset the routine arrangements for vaccination and revaccination. Another factor favouring recent small-pox in Germany has been the presence of large numbers of unvaccinated Russian prisoners of war, whom, even after the cessation of hostilities, it was impossible to repatriate. Very little information has come to hand from Austria, but small-pox is known to have been recently prevalent in Vienna, Prague, and other places. At Budapest, the Hungarian capital, there has been a sharp outbreak of the disease. Italy of late has been, and still is, suffering from a widespread epidemic of small-pox. In the seven weeks' period ended July 6th 4645 cases of the disease were reported. During the month of June small-pox occurred at some Italian ports, including Bisceglia with 232 cases and Taranto 335 cases, both ports being situated on the Adriatic coast of the province of Bari. At the

Sicilian port of Trapani 230 cases were notified during the month. Outbreaks also occurred at a number of towns, including Naples and Pagani. In Greece small-pox has been prevalent at Salonica, where 42 deaths have been certified from it; cases have also been occurring at the port of Cavalla and on the island of Corfu. There has been a recent epidemic of small-pox in Roumania, and in the four weeks ended July 15th 1595 cases were reported with 553 deaths, giving the high fatality rate of 34.6 per cent. The disease was also present at Bucharest and Jassy, as well as at the ports of Galatz, Braila, and Constanza.

Owing to the Bolshevik regime in Russia little information is allowed to pass over the frontier as to the incidence of infectious diseases. It is, however, a well-known fact that for many years small-pox has been more prevalent in Russia than in any other European country. With the suppression of sanitary administration and the disregard of scientific advice by those now exercising power in various parts of Russia, small-pox has become more prevalent at the present than in the past. Indirectly we have heard that the hæmorrhagic form of small-pox, notoriously attended with great mortality, is epidemic in the town of Simbirsk, which lies about 400 miles east of Moscow. In Southern Russia outbreaks have occurred at Ekaterinodar, in the province of Kuban, and at the Black Sea port of Novorossick, some 90 kilometres from Ekaterinodar. Small-pox is at present epidemic in Finland, and during the first three months of this year 778 cases were recorded, 372 of which occurred in the province of Viborg, which adjoins the Russian Government District of Petrograd. In Sweden small-pox has appeared at Stockholm and also in Denmark at Copenhagen. The disease, though not in large amount, has been reported to be present in Belgium during each of the first five months of 1919. There have been recent outbreaks of small-pox in France, and among the places invaded were Paris, Toulon, Brest, and Havre. Spain frequently suffers from epidemic small-pox, and in the present year some of the large towns were affected; in Madrid, for example, 81 deaths from this cause were reported during the first quarter, and outbreaks also occurred in the Spanish ports of Cadiz, Barcelona, and Valencia; at the last-named port 568 cases were recorded in the first three months of 1919. The disease had been epidemic in Portugal towards the end of 1918, and this continued during the first half of the present year, 160 cases being reported at Oporto and 116 at Lisbon. Little information has come to hand from Turkey, but indirectly we hear of small-pox having occurred recently in Constantinople, as well as in some places in Western Anatolia. In addition, as the voyage to England from Egypt can be done in less time than is represented by the incubation period of small-pox, there is a possibility of the infection being introduced into our own country from this source before the disease can be recognised. Up to the beginning of June close upon 3000 small-pox cases had been recorded in Egypt, and of these 500 occurred in the fortnight ended June 10th.

It is probable that if the pre-war sources of information had been available now the above details of the small-pox incidence would have been greatly extended. But the figures we have given will suffice to show that many countries in Europe are now suffering from small-pox, and that a

number of ports in the Mediterranean and along the Atlantic shores of Europe, as well as in the Baltic and Black Seas, are infected by small-pox, and therefore possible sources of infection for this country. Meanwhile, the disregard in England of vaccination and revaccination continues as before, and the unprotected proportion of the people increases day by day. In THE LANCET of Aug. 16th Dr. W. McCONNEL WANKLYN, a recognised authority, gave some useful notes on small-pox for the assistance of general practitioners. He directed attention to the numerous outbreaks of the disease which have occurred this year in England and Wales, due in some instances to imported infection. He emphasised the importance of a correct diagnosis, missed diagnosis being a frequent source of the spread of the disease. In the same issue we reproduced a memorandum recently sent out by the Ministry of Health on "The Public Supply of Vaccine Lymph," explaining how lymph may be obtained without delay, by those medical officers who are called upon to deal with local small-pox cases, for the vaccination or re-vaccination of contacts and other persons in the invaded locality. This memorandum is timely, and will prove of service to those concerned. As we have already stated, the small-pox danger is more likely to become acute in this country in the latter months of the year.

### Food Preservation in Relation to Accessory Factors.

THE busy and fruitful researches which are being carried on at the present time in regard to the kind and degree of accessory factors in the common dietary are rapidly suggesting that our methods of food preservation in some directions need revision. For example, it is shown that the value of canned vegetables in regard to antiscorvy and growth-promoting properties is negligible. That, at all events, is the purport of an investigation which we publish this week by Dr. MABEL E. D. CAMPBELL and Dr. HARRIETTE CHICK. It is here shown that in the case of runner beans the antiscorbutic value of 20-g. was reduced by canning to less than that of 5 g., and was not superior to 1.5 or 2.5 raw beans. In other words, this preserving process means that 75 to 90 per cent. of the antiscorbutic value had been destroyed. In the case of cabbage the loss is estimated at about 70 per cent. of the original value. This loss is attributed to the destruction of antiscorvy factors occurring during the heating involved in the process of canning, and a further loss occurs during the period of storage. In the case of green leaf vegetables possessing in addition to the antiscorvy vitamine the growth-promoting accessory factor, this was also lacking in the canned material, but was present in the liquor. It would seem undesirable, however, to take the liquor on the ground conceivably that it might be contaminated with metal, though this difficulty may be got over by lacquering the tins, as is done in some cases, or coating them lightly with an innocuous varnish. The results in regard to the deterioration in canned vegetables in growth-promoting and antiscorvy factors are strikingly brought out in a table. In the majority of instances the process of canning reduced the protective power against scurvy to a negligible quantity and the growth-promoting properties were likewise much diminished. The well-known method of preserving vegetables by brine and vinegar is not referred to;

nowhere in these important researches do we find pickles mentioned. It would be interesting to have determined whether the activities of the food accessory factors in vegetables preserved in salt and vinegar are disturbed. The investigation should of course include walnut, cabbage, onion, beetroot, all of which, in their fresh state, are protective against scurvy. In the records previously published<sup>1</sup> pickles appear to have been disregarded. Admirable additions to certain foods, it would be interesting to discover whether they fill a gap also by supplying accessory food factors. If so, there is greater reason for consuming them than on the mere ground of condimental value. Pickled vegetables, of course, may well be distasteful to the animals selected for the experiments, but this technical difficulty occurred in the investigation of dried fruits, when it was overcome by making decoctions, the liquor obtained being administered to the animals by means of a syringe. The same procedure, perhaps, could be adopted with pickles, and an evaluation of antiscorbutic and growth-promoting principles obtained.

In a second contribution by Dr. HARRIETTE CHICK, Miss E. MARGARET HUME, and Miss RUTH F. SKELTON on the Antiscorbutic Value of some Indian Dried Fruits it is shown that the dry tamarind, cocum, and mango possess a definite but small antiscorbutic value. This value is greatly inferior to that possessed by raw cabbages, swedes, germinated pulses, orange juice, lemon juice, but equal or superior to that of carrots, beetroots, cooked potatoes, raw meat juice, reckoned weight for weight in the natural conditions. This investigation was undertaken early in 1917, at a period in the war when scurvy was proving a serious menace to our native troops in Asia. In the Afghan Boundary Commission in 1884-1886 it was observed by Major-General Sir HAVELOCK CHARLES that a freedom from scurvy was enjoyed by the native soldiers who consumed dried mango when fresh fruits or vegetables were not procurable, and these investigations show that the dried mango is to some extent protective, but with nothing like the power of fresh fruit or their juices.

Some valuable observations, again, occur in a third contribution on the subject by Miss ROSAMUND E. BARNES and Miss E. MARGARET HUME, who have in their investigation set out an interesting comparison between the antiscorbutic properties of fresh, heated, and dried cow's milk, the subjects of these nutritional experiments being guinea-pigs and monkeys. The dried milk used was prepared by a process involving the use of a high temperature, which, amongst other things, destroys enzymes, coagulates albumin, and separates fat. It would be well before deciding upon the position of dried milk to examine the milk powder obtained by the spray process, which, being conducted at a relatively low temperature, may possibly secure the retention of antiscorbutic principles. If so, an important differentiation between these methods of drying may be established. At the outset cow's milk, even when fresh, proved to be a foodstuff comparatively poor in antiscorbutic properties. Dried milk was still less protective, and "scalded" milk was superior to it. This observation bears, of course, upon the practice of just boiling milk and setting it to cool rapidly before giving it to infants. Apparently, however, raw milk varies in its accessory food factor value according to whether the cow has received a winter dietary (hay, roots, oil-

<sup>1</sup> THE LANCET, July 5th, 1919, p. 23.

cake, and cereals), or the early summer dietary of fresh grass from the open pasture. In other words, the great increase of antiscorbutic material in the latter diet resulted in a corresponding increase in the antiscorbutic value of the milk given. It is true that these observations are not based on experiments on the human subject, and as Mr. E. A. BARTON points out in a letter published in another column, there seems to be no doubt that animals suffer from the deprivation of the antiscorbutic vitamin in their food much more rapidly and severely than does the human infant. It is to be remembered that the animal diet in the main is raw and growing food. Whether the human mother is able to transmit a tolerance in her infant to a diet poor in vitamins, or whether the human young require much less than other animals to keep them in health is, as Mr. BARTON points out, pure speculation; but there is a probability that when infantile scurvy has advanced to the stage of physical signs we have arrived at the last chapter of the disease and not the first. A valuable region of study in dietetics is being opened up by these investigations.

## Unqualified Treatment of Venereal Disease.

AT the London Sessions recently two men, J. SHADFORTH and J. WILSON, were convicted and sentenced to imprisonment in the second division for four and three months respectively, for offences against the Venereal Diseases Act, 1917. The Act, it will be remembered, forbids the treatment of venereal disease by persons who are not qualified medical practitioners, in areas in which the Act is adopted and in which gratuitous treatment for such disease is provided. The Act also forbids the advertisement of treatment and alleged remedies for venereal disease. The defendants were described as "chemists," engaged in a business conducted under the name of Shadforth's Prescription Service, Ltd. SHADFORTH called himself the "governing director," and stated that he employed a staff of 50 persons. The nature of the business transacted by "a prescription service" is probably indicated by its name and by the fact that SHADFORTH advertised in a daily newspaper a variety of alleged medicines for the treatment of disease, including one described as prescription 606, with a recommendation of it as a "bad blood tonic." In a pamphlet, the purchase of which was recommended by the same advertisement, occurred the passage "even syphilis in most instances can be cured by the patient himself, with practically no supervision, provided he is told at the outset in plain English what to do and what remedy to take." At SHADFORTH'S shop detectives were able to purchase tablets purporting to be those advertised as 606, and one of them was told by WILSON that it was the best he could have for syphilis. As to the tablets being advertised for bad blood without mentioning syphilis, WILSON explained: "Well, we could not put that in, could we?" As a point of law it was submitted that the section of the Act involved referred to actual dealing with a person affected by venereal disease, and that there was no evidence of treatment, prescription, or the giving of advice. Mr. LAURIE, the deputy chairman, however, declined to withdraw the case from the jury, with the result recorded above. The verdict followed after SHADFORTH had himself gone into the witness-box and had stated with considerable

candour that he had done his utmost to oppose the passing of the Venereal Diseases Act, 1917, by writing letters to Members of Parliament, and even by standing himself as an independent candidate for election to the House of Commons. Since the Act became law he had written to every Member of Parliament to inform him that he intended to defy the Act, but he alleged that he had since changed his attitude and had decided to comply with the law, although continuing to protest. He denied that he had advertised "606" with any intention that it should be taken to have any relation to salvarsan, and said he had forbidden his assistants to sell remedies for venereal disease. He admitted, however, that in a letter to Sir EDWIN CORNWALL he had written, "For many years I have openly, honourably, lawfully, and successfully supplied the remedies and treatment for venereal diseases."

The result of this prosecution is one upon which the public and those concerned in the passing of the Venereal Diseases Act, 1917, are to be congratulated; the case shows "Shadforth's Prescription Service, Ltd.," to be one of those institutions conducted for profit, and no doubt with considerable profit, the activities of which are dangerous to sufferers from venereal disease, and so to the public. SHADFORTH said in the witness-box that he had made a special study of venereal diseases. No doubt he had, from his point of view. If he had studied them from the point of view of the medical profession, however, he would have recognised willingly that syphilis and gonorrhoea and their complications cannot, consistently with the welfare of the patient, be dealt with by a shop assistant selling tablets over a counter, or posting them, to one who applies for them in response to an ingenious advertisement. We are writing of particular diseases for sufferers from which a limited form of protection has tardily been provided by Parliament. Our view and that of the medical profession is, however, without any qualification, that whatever may or may not be the matter with the patient, he cannot be treated properly, and he ought not to be treated at all, by an unqualified person, who sells him a nostrum for profit in response to his statement that he is suffering from —. He may name any disease from which he fancies that his symptoms proceed, and, indeed, he may name it correctly, but a physician before prescribing for him would require to know more about his condition than that. Diagnosis is not as simple a matter as the labelling of the bottles and pill-boxes that the quack sells. Of course, in trifling cases, or where the patient has nothing the matter with him, the credulous purchaser may suffer only in his pocket. He may be sold something which, if costly, is quite harmless; but even then he is likely to acquire a habit of self-treatment that may one day prove his undoing. All this is quite well known to the medical profession, but we comment on the case because these are the sort of incidents that our readers ought to bear in mind when advocating firmer legislation in the repression of quackery.

## INDEX TO THE LANCET.

(VOL. I., 1919.)

WILL those subscribers who have written to the Manager asking for copies of this Index kindly note that it was given in the issue of THE LANCET of July 5th and is not printed separately, thus reverting to pre-war custom?

## Annotations.

"*Ne quid nimis.*"

### "THE OSLER MEDICAL LIBRARY."

A DISTINGUISHED foreign physician attended the recent Osler presentation ceremony at the Royal Society of Medicine, fully believing that the undergraduates from the University of Oxford would be present in swarms and that the occasion would be marked by noisy demonstrations in honour of a great teacher. He was not so much disappointed as puzzled by what actually happened. No noisy students were present and the proceedings were simple, dignified, and not unmarked by a touch of pathos in Sir William Osler's charming and characteristic reply to Sir Clifford Allbutt, after the latter had handed him the Birthday Book. Sir John MacAlister struck a right note in the chorus that greets the Regius Professor of Medicine at Oxford on the occasion of his seventieth birthday. This contribution to the Osler Birthday Book is a brilliant essay in Utopianism. Sir John MacAlister dreams a dream and imagines himself the guest of the librarian of an ideal Osler Medical Library, situated in Regent's Park. It is a palace with a Greek portico, and in the centre of the great inner quadrangle stands a noble marble statue, which at first the dreamer mistakes for the "Hope Asklepios," but soon recognises as a living, smiling William Osler. "I could have sworn," he says in ecstasy, "that one of those wonderful eyes solemnly winked at me." The wink gives the cue to the further experiences inside the remarkable building which contains a magnificent collection of books, besides printing presses, a bindery or binding-room, telephones galore, and a system of pneumatic tubes so designed as to drop volumes at the proper instant of time in front of the pampered researchers at their desks in the large main library. These tubes manifestly do the work of the grey matter in the brain: they are the thinking machine of the ideal library. Librarians are there, it is true, but we feel from the first that these persons are only a kind of mechanics or tradesmen of books, however much they may be renowned as specialists in particular branches of medical and surgical learning. The poor fellows, harassed at all hours of the working day by telephone calls, will take their meals together in a refectory and talk shop there to the ruin of their digestions and of general conversation. The noble library is very nearly dust-free, and apart from its wealth and variety, this is the best thing a library can be. The grand aim of a librarian in his house-keeping capacity should be the complete deportation of dust from his precincts, but in too many cases dusting of books only creates a local dun-coloured cloud which re-settles in the old situations. In the "Osler Medical Library" dust is removed from the volumes by damp clean sawdust which is sprinkled on their top edges: this gathers up the book-dust to be swept off the floor clinging to the particles of sawdust. In a dream the process is fine, but is it not a little perilous? Damp sawdust is difficult to regulate. If a little too wet it cakes and exudes small drops of water, which would be fatal to fine bindings. "Pulvo," fitted with the proper shape of nozzle, is the advice of our own dreamer of the model library. But Sir John MacAlister need not be taught any lessons about "pulvo," though we should like to

learn if he has any criticisms to offer, for his article is full of practical suggestions. All he tells us about the manner in which an ideal library should be catalogued is admirable, and we are glad to know that this dream-system is already virtually in use in some of the great scientific libraries. Admirable, too, is his suggestion that the records of research in the shape of literatures and bibliographies made by medical authors should be preserved by librarians. At his own library this, we believe, has been done for some years, while at the library of the Royal College of Surgeons of England Mr. Victor Plarr has catalogued all bibliographies and literatures in the printed books under his charge. This catalogue of bibliographies is a large one and has proved most useful to researchers, among others to Sir William Osler.

### ALCOHOL IN A NEW RÔLE.

THERE are some points of medical interest in the proposal to bring alcohol into prominence as a source of power. Incidentally the moment that facilities are given for its production on a large and economic scale its application would not be limited to traction and like purposes, for cheap alcohol would give an immense stimulus to many industries dependent upon it as a solvent. Alcohol for general industrial purposes, however, must be made undrinkable. The de-naturing of alcohol so that it shall be made unfit for consumption offers no difficulty, though, of course, precaution must be taken that the altered alcohol cannot be again purified and used as potable. At present the process of rendering industrial alcohol undrinkable adds materially to its cost, but recent inquiries have shown that the price of the deterrents can be considerably reduced, and our legislators could further help in this matter by imposing much heavier penalties than those now sanctioned by law for evasion of the spirits duty in any case of illicit purification of "power" alcohol to render it potable. The question is of undoubted importance, when it can be shown that although the United Kingdom may be unable to supply enough raw material to make the manufacture of "power" alcohol a commercial success, the resources of its dominions in this regard are potentially very great. The vegetable sources in the British Islands afford but a poor stock of material for the manufacture of alcohol. But in this matter the Empire could come to our aid most effectively with its vast carbohydrate productive capacity. Apart, however, from that great asset, chemists have recently turned their attention to the possibility of producing alcohol synthetically, and the results are so far promising. The starting point is coal gas or coke-oven gas, which contains a small though not negligible amount of ethylene. This can be removed by charcoal without disturbing materially the quality of the gas. The charcoal then is immersed in molten lead, which drives out the gas, which, as most students of chemistry know, was the basis of the synthesis of alcohol many years ago. That this process should be advanced beyond its stage of flask and still in the laboratory, and become a commercial proposition to-day, is a matter of some wonder even to the chemist himself. In many text-books will be found the statement that these reactions are of considerable theoretical importance, but now we are told it has been demonstrated that our gas-works are capable of yielding annually 150 million gallons of 90 per cent.

alcohol by this synthetic process, which has been proved to be commercially workable. Ethylene ( $C_2H_4$ ) is absorbed by sulphuric acid to form ethyl hydrogen sulphate. This, boiled with water, yields alcohol and sulphuric acid again. Distillation completes the process. The catalyst, that mysterious third party in chemical reactions, has been made to intervene, and the yield of alcohol then becomes greater than of "theoretical importance." Alcohol will play an entirely new rôle in our industrial and domestic affairs if these things be true.

#### A REMINISCENCE OF WILLIAM HUNTER.

Dr. Alexander Napier, the honorary librarian of the Royal Faculty of Physicians and Surgeons of Glasgow, has published in the *Glasgow Medical Journal* for July an interesting note concerning William Hunter. Dr. Napier numbers among his friends a certain Mrs. Kean, whose family is connected with the Hunters through Archibald Hunter, an uncle of William and John, and from a grandson of this Archibald Hunter, another William Hunter, she received the relics which form the subject of the memorial. They are a letter and a portrait. The letter, dated Windmill-street, March 20th, 1782, is written to one Robert Barclay, evidently in response to one from him asking Hunter to intercede with the Queen on behalf of a seaman who had been condemned to death. Hunter refused on very sound reasoning. The other relic, the portrait, is a copy of a stipple engraving by Thornthwaite, and is well reproduced in Dr. Napier's paper. It shows, as Dr. Napier remarks, a different type of face from the better known portraits, which are characterised by elegance and grace. The Thornthwaite portrait is that of a masterful and determined man.

#### DENTAL TREATMENT AND NATIONAL HEALTH.

In the report issued by the Departmental Committee on the Dentists Act attention has been drawn to the necessity of enlightening the public by every possible means as to the need for conservative treatment of diseased teeth. A committee of the British Dental Association has recently considered how this could best be carried out, and has embodied its views in a pamphlet which, we believe, has been circulated amongst education and public authorities. The committee, after due deliberation, are of the opinion that it is impossible, owing to the present condition of the dental profession, to formulate an extensive system of State dental service, and consider that, in the first place, every endeavour should be made to obtain a complete school dental service. For the latter purpose they recommend, as a rule, whole-time officers, and are of the opinion that on the staffs of the Educational Departments of England and Scotland there should be dental officers responsible for the work done in local educational areas. For the treatment of expectant mothers and of children under school age they suggest, if possible, the appointment of whole-time dental officers, and the institution, where possible, of central laboratories for the provision of dentures. The requirements of the adult population, they think, might for the present be met by an extension of the system of factory clinics, by affording support to the public dental services established by members of the profession, and by the creation in certain large industrial areas of experimental clinics. The report shows very clearly the difficulties of pro-

viding an adequate service for the whole community. It quite rightly emphasises the desirability of treating children of school age, but we consider that, important as this is, there is a greater need to deal with those under school age, for in the children of the masses irretrievable damage has often been done to the teeth before school age. A feasible plan would, we think, be to co-ordinate the work of the children's welfare committees with that of the school authorities, and make it possible for those under school age to be treated by the school dental officers. In reading the report we feel that by no means sufficient consideration has been given to the question of prevention. If we are to obtain an improvement in the condition of the teeth of the nation, it will be by teaching the individual to prevent the condition and not to rely upon a cure. One trouble is the indifference of the majority to the question of dental disease, and this can only be overcome by widespread propaganda on the harm which arises therefrom. The establishment of free public lectures and the issue of a small pamphlet written in popular language would prove of inestimable value. By this means the amount of disease would be considerably lessened and there would be a corresponding diminution in the amount of conservative dentistry required.

#### THE METROPOLITAN HOSPITAL SUNDAY FUND.

At a recent meeting of the Council of the Metropolitan Hospital Sunday Fund the Distribution Committee reported that the total amount of the Fund on August 11th would amount to £83,000, of which it recommended the distribution of £82,462 13s 8d. The amount will strike many as large, having regard to the financial situation produced by the war. Others will compare it with far smaller sums which were regarded as satisfactory totals not many years ago. If, however, we contrast its purchasing power with that of a sum of £50,000 or £40,000 before the war we realise that, generous though the public may have been in subscribing, the hospitals will receive allotments small in value by comparison with those of the past. Hospitals have been hardened to rigorous economy, but their need for it has become even greater in an epoch when science has increased their powers of usefulness and when the ravages of war have augmented the number of patients likely to crave their aid. It is a recognised function of the Metropolitan Hospital Sunday Fund to promote economy of management, and a timely recommendation of the Distribution Committee suggests that in some cases where two or three cottage hospitals are within a reasonable distance of one another they should be recommended to amalgamate with a view to more economical working. The Committee points out that the relatively small proportion of occupied beds appears to account for the high cost of treatment shown at some cottage hospitals. The recommendation is in all the circumstances a sound one. The sums allotted to individual cottage hospitals amount in some instances to between £100 and £200, the smallest being under £20. These are not large amounts for the supporters of a cottage hospital to make up if they should prefer to retain as exclusively local an institution of which they are naturally and justly proud. They might then reject with a clearer conscience the advice of the Distribution Committee, and refuse amalgamation, although the resulting economy

would mean obtaining the best possible result for their money. Apart from such voluntary renunciation, the Distribution Committee has, of course, the right to refuse to allocate money where it is not satisfied that economy is practised.

#### "THE DANGERS OF THE NEW PUBLIC HEALTH ACT."

UNDER the above heading appears an article in the July number of a well-known Roman Catholic organ, *The Month*, which shows the apprehension with which legislation, apparently good in itself, excites among a large section of our fellow-citizens. The writer takes exception to the new Act (its proper title is the "Ministry of Health Act, 1919") on two main grounds, namely:—"A. The respects in which this Act is liable to abuse through administrative action (1) on account of, perhaps, accidental vagueness in the text, or (2) on account of phrasing apparently designed to admit of large modifications in administration. B. The actual violations contained therein of (1) general first principles, and (2) definite and precise Catholic doctrine." We are in sympathy with the writer in *The Month* as to the provision made for legislation by Orders in Council, a procedure of which we have seen far too much during the war, but he is in error when he says that provision for legislation of this character is made in "no less than seven of the 11 clauses of the Act." As a matter of fact Orders in Council are only mentioned in three of the 11 clauses—namely, Clauses 3, 4, and 8—though in fairness we must allow that provisions for Orders in Council in Clause 3 are very wide-spreading. As regards objection B, we think he is somewhat in the mental condition of those who worry about crossing the river before they come to the bridge, and we doubt whether the views of extreme "Eugenists" will affect the working of the Act as much as he fears. Anyway, we recommend him to reconsider his judgment until the appearance of the Medical Services Bill. With regard to the question of "birth control," upon which he lays special stress, we recommend to his attention a work by his co-religionist, Dr. C. Capellman, seventh edition, 1890, entitled, "*Medicina Pastoralis*."

#### COMMON LANDS AND MEDICAL USAGE.

DOUBTS are being expressed by the press and members of the public as to the effect upon common lands which may be produced by the provisions of the Land Settlement (Facilities) Bill now before Parliament. Lord Eversley, in a letter recently published in *The Times*, pointed out that although various safeguarding amendments proposed by the Commons Preservation Society have been accepted by the Board of Agriculture, whereby no part of a common or open space vested in a local authority can be alienated without Parliamentary sanction, and no rural or suburban common without the consent of the Board of Agriculture, yet the reclamation schemes included in the Bill constitute a real and serious menace. For the schemes will be initiated by a department of the Board itself, and there will be no appeal from any decision of the Board to acquire and enclose a common. We are glad to know that local authorities must obtain the consent of Parliament to alienate a common, for in past times local authorities have not hesitated to get hold of common land for use as the site of a cemetery, a

sewage farm, or an isolation hospital. It is true that all three institutions are necessities of modern civilisation, and are all abominations in a thickly populated district; but there is plenty of practically barren land in private ownership which should be taken up before common lands are alienated, either with a view to their being turned into cultivated land or used as building sites. There is no clause in the Bill providing that the land shall be restored as common if cultivation proves unsuccessful, and this, surely, is an error. Much common land was put under cultivation with very good results during the war, but then the circumstances were such as to make the experiment likely to succeed. For instance, some 30 or 40 acres of Ashdown Forest were put under cultivation by the military of a large camp. Two essentials of successful cultivation were present—namely, labour and manure—and magnificent crops were grown. The land is too far away from the neighbouring village to serve as allotments and the conservators of the forest have insisted on the land going back to its original condition now that the camp is practically broken up. They have arguments on their side, though they may not be irrefutable. Commons and forest lands are of the greatest importance to the welfare of the community not only as "open spaces" but as pasturage, and sources of litter—e.g., heather and bracken. They are sanctuaries for insect-eating birds, which are of enormous value to agriculture, for every crop is not as assailable as a cherry, nor every bird as mischievous as a bullfinch. So long as other land can be obtained of equal suitability, commons should be exempt from alienation, and economy in purchase is a secondary consideration. But where it is a question between public health and pleasant amenities public health must be allowed to win.

#### THE RAISING OF THE INCOME FOR COMPULSORY INSURANCE.

THE attention of employers is being called by the Ministry of Health to the fact that by the National Health Insurance Act, 1919, which has just received the Royal Assent, the limit of remuneration up to which persons employed otherwise than by way of manual labour are liable to compulsory health insurance has been raised from £160 to £250 a year. Employers are required for the future to pay health insurance contributions in respect of persons employed by them under a contract of service as follows: for non-manual workers, where the rate of remuneration (including any regular bonus, &c.) does not exceed £250 a year; for manual workers, irrespective of the rate of remuneration. A non-manual worker whose remuneration is over £160 a year but not over £250 a year may, within a limited period and under certain conditions, claim a certificate of exemption, and on the grant of such a certificate the employer's contributions (3d. a week) are alone payable. Forms of application for exemption will be obtainable shortly at any post office.

ST. THOMAS'S HOSPITAL, LONDON.—The following scholarships have been awarded: Entrance Science Scholarships, 1919-20: 1st, £150, T. V. Pearce; 2nd, £60, E. G. L. Walker; Arts Scholarship, £15 15s., M. W. P. Hudson; Musgrove Scholarship, £35, F. J. Hackwood; William Tite Scholarship, £25, E. G. Housden.

## REGISTRAR-GENERAL'S DECENNIAL SUPPLEMENT (1901-1910).

### II.

UP to the close of last century the diseases returned as causes of death were classified at the Central Office according to the system adopted by Dr. William Ogle. But in 1901 this system was modified by his successor, Dr. John Tatham, in order to co-ordinate the national records with the revised Nomenclature of Diseases promulgated at that time by the Royal College of Physicians of London. Only a few of the headings in the tables are affected by this modification, the list of diseases having been rearranged with a view to the preservation of continuity. Under the present scheme of tabulation the number of deaths assignable to a particular heading is determined by the rule that out of several causes of death mentioned in a certificate only one disease is to be selected for registration. Greater precision of certification has recently led to increased transference of deaths from indefinite to definite headings. Transfer on these lines has been materially aided in recent years by the judicious practice of appealing from the Central Office to medical certifiers for additional information in cases of deaths imperfectly attested. As a result of this expedient it is stated that in the course of last decennium more than 5000 additions were made to the entries both of tuberculosis and of cancer, and more than 1000 each to those of puerperal sepsis and appendicitis.

The Registrar-General highly appreciates the co-operation thus rendered gratuitously by the medical profession, without which correction of this kind would obviously be unattainable.

#### *Mortality at Different Stages of Life and in the Two Sexes.*

From an instructive series of tables we learn how the chief fatal diseases stand in relation both to one another and to the age constitution of the victims. The proportions, having been calculated on the facts of ten years, may be regarded as resting on a fairly reliable basis.

According to the experience of 1901-10 not less than 10.8 per cent. of the total mortality is due to tuberculosis, a larger proportion than that attributed to any other single cause. From age 15-20 onwards the bulk of this mortality is due to the pulmonary form of the malady. Next to tuberculosis stands heart disease, accounting for nearly another 10 per cent. Following these in order of importance the remaining chief causes of death are pneumonia, bronchitis, cancer, disease of blood-vessels, and diarrhoea. At ages 10 to 20 and 35 to 55 heart disease ranks second in order as a cause of death, while in the intervening period, 20 to 35, it ranks third. Thus for the greater part of life these disorders of the circulation, when they do not actually occupy first place, come second only to tuberculosis as causes of death. The second place is occupied by pneumonia at ages 0 to 5 and 20 to 35, by diphtheria and croup at 5 to 10, by cancer at 55 to 65, by diseases of blood-vessels at 65 to 75, and by bronchitis at ages above 75. At ages 25 to 65 pneumonia and appendicitis are most fatal to males, and whooping-cough, heart disease, and cancer to females.

The familiar epidemic diseases are generally more destructive to life in the first five years than in the whole remainder of life. This is particularly noticeable in the case of whooping-cough, measles, scarlet fever, diphtheria, and diarrhoea. With reference to the behaviour of these epidemic diseases in later life, and to the fact that adult mortality thus caused is generally greater amongst females, Dr. T. H. C. Stevenson suggests that this may be due to their more frequent exposure to infection through sick nursing and other family duties. He finds that adult mortality from scarlet fever and from diphtheria is higher among women, whereas from small-pox, enteric fever, and cerebro-spinal fever it is considerably higher in men, among whom the risk of infection from domestic sources would often not be so serious. The incidence on the sexes of mortality from small-pox and enteric fever does not greatly differ throughout childhood, but on the attainment of adult age the mortality of males far exceeds that of females. This is also true of pneumonia.

*Streptococcus diseases.*—This group, including erysipelas, septicæmia, pyæmia, and phlegmon, with carbuncle and

cellulitis, may be said to possess in some sense a common type of age distribution, about 25 per cent. occurring in the first five years, and the remainder being widely scattered over the rest of life. But whilst the *local* infections are seldom dangerous to older children and young adults, the *general* infections, pyæmia and septicæmia, are very fatal during youth and correspondingly less fatal in old age.

*Syphilis.*—General paralysis of the insane and locomotor ataxy being now regarded as particular manifestations of syphilitic infection, much attention has recently been devoted to these diseases. The total mortality from the first of these conditions is more than three times as heavy for males as for females. There appears to exist little difference between the sexes in regard to the loss of life thus caused among young persons, the higher proportion of juvenile to total mortality in the female sex being due to the lower aggregate mortality of females. We learn that at ages below 20 years, when the disease originates in congenital syphilis, which affects both sexes alike, males and females are equally liable; but that at ages above 25 years, when most of the cases are due to acquired syphilis, the remarkable excess of male mortality becomes evident. The same feature obtains in a less degree in the case of syphilis itself, and it may be that the suppression of facts which notoriously prevails in regard to that disease affects men more than women. That sex has a real influence on mortality arising from syphilitic taint appears from comparison with locomotor ataxy. Although both this disease and general paralysis have a common origin in syphilitic contamination, the excess of male mortality is considerably greater in the case of locomotor ataxy. Moreover, the tendency of approximation of female to male mortality in old age, which is apparent in the case of syphilis as well as of general paralysis, is believed to be absent in the case of locomotor ataxy.

*Tuberculosis.*—The most striking feature of these tables is the prominent position occupied by tuberculosis, which at ages from 5 to 55 accounts for more deaths than any other single cause. Between the ages of 20 and 25 it causes more than 40 per cent. of the aggregate mortality in both sexes. The deaths assigned to tuberculosis in 1901-10 amounted to 565,161, and were fewer by 50,845 than in the previous decennium. Corrected for estimated increase of the population the difference becomes 121,941. The life saving claimed may be still further increased if allowance is made for the fact that the constitution of the population in the recent decennium was more favourable to tubercle mortality than had been that of 1891-1900.

The standardised death-rate in 1901-10 was equal to 1646 per million living, or 18.6 per cent. less than in the decennium immediately preceding. During the 50 years elapsed since 1861-70, tuberculous mortality has been nearly halved among males and more than halved among females. The greatest reduction among males occurred at ages 10-25, and among females at ages 15-45. At ages 45-65 the mortality of women has fallen more than twice as much as that of men.

From the degree in which tuberculosis has contributed to the total deaths at various ages during the last 60 years it appears that the disease is now of less relative importance as a cause of death than in earlier years. This change is much more conspicuous amongst females. It applies in each sex to all ages, except 5-10 and 10-15, when mortality from all causes is relatively low. The ages at which tubercle contributed most to the total death-rate ever since 1860 have been 20-35 for males and 15-25 for females. At the latter age it accounted for rather more than half the total deaths of females during 1851-70, but this proportion has recently fallen to a little over 40 per cent. At all adult ages the disease now plays a more important part in the mortality of males than of females, although during 1851-70 this was the case only at ages above 45. The concentration of tuberculous fatality upon the most valuable working period of life is a startling fact which should receive the earnest attention of the new Minister of Health, to whom it may be suggested in the words of the text, that "the period of early maturity which is specially attacked in both sexes is that at which the proportion of future productivity to dependence is at its maximum, and at which, therefore, deaths are the greatest loss to the community."

#### *Changes of Mortality in Three Decennia.*

Hitherto the study of disease incidence and mortality has been limited in these pages to the experience of a single

decennium. But Dr. Stevenson now furnishes us with the means of tracing the changes of this incidence in the course of the three successive decennia from 1881-90 onwards. The standardised death-rates in each of the last three decennial periods are compared with the aid of a table from which it appears that for all causes jointly a decrease of 16 per cent. in 1891-1910 has succeeded to a decrease of 3 per cent. only in the decennium immediately preceding.

The following are the principal declines in mortality recorded during the last 30 years—a period nearly corresponding to that which has elapsed since the passing of the great Public Health Act. From enteric fever the fall has been equal to 48 per cent., from influenza to 43 per cent., from diphtheria and croup to 36 per cent., from bronchitis to 36 per cent., from puerperal septic diseases to 34 per cent., from gout to 32 per cent., and from pleurisy to 31 per cent.

As against these large declines, as well as many others of a substantial nature, the only important increases recorded are those from cancer, diabetes mellitus, and Bright's disease. Of these by far the most important is the increase of cancer, the standardised rate for which is higher by 13 per cent. than in the previous decennium, this increase being only at half the rate shown in the preceding period.

It is significant that the two chief diseases for the recognition of which examination of the urine is important, diabetes and Bright's disease, are both included in the short list of recorded increases. Such aids to medical diagnosis are no doubt more generally practised by physicians as time goes on, and Dr. Stevenson regards it as quite conceivable that this fact may largely or wholly account for the increase shown in the tables. The slight increases recorded from valvular heart diseases and from angina pectoris may be dismissed as due merely to improvements in certification, seeing that diseases of the heart and blood-vessels in the aggregate show a considerable reduction. For a similar reason the slight increase from pneumonia may be also dismissed.

## TUBERCULOSIS IN ITALY.<sup>1</sup>

THE American Red Cross Commission on Tuberculosis in Italy entered on its inquiry with three guiding principles of action: "First, that no wise plan of coöperation could be drafted in a foreign country without first gathering intimate knowledge of its people and of existing health conditions; second, that no matter how well trained men and women might be for work in America, this was not necessarily an indication of their preparation for work in a foreign country; third, that sympathetic relations between workers and people must be developed through the avenue of mutual knowledge." A long course of preliminary study was accordingly undertaken before the actual work was entered on; and, indeed, the entire investigation appears to have been conceived and carried out in the most thorough and exhaustive manner possible.

### *Mortality from Tuberculosis in Italy Compared with other Countries.*

The mortality from pulmonary tuberculosis in Italy was 115 per 100,000 in the quinquennium 1909-1913, the same as in Scotland and the Netherlands; in Ireland and in Norway it was 173; in England and Wales it was 105; in Belgium (1908-1912), 99; in France (1907-1911), 183. Though there are 20,540 beds available for tuberculous soldiers and discharged prisoners, it is stated that more than half are unoccupied, and that in Sicily a hospital with 800 beds has only five patients. Hospital life and its restrictions are said to be disliked by the Italians. Although the tuberculosis question is therefore not so serious as in some other countries, the decline in mortality from this cause has not been satisfactory during the last 50 years, and during the war there has been a larger proportional increase in spite of favourable conditions of climate.

### *Scope of the Inquiry.*

In view of existing organisations of the Italian Red Cross and the Government, the American Commission decided, after careful inquiry, to limit their work to the provinces of Liguria, Umbria, Palermo, and the island of Sardinia. The ideal organisation that was aimed at comprised these four

sections:—Public health, Antituberculosis methods, Child welfare, and School hygiene; and committees were appointed to deal with (1) hospitals and sanatoriums, (2) dispensaries, (3) teaching of general hygiene, (4) finance, (5) medical instruction, (6) research into social conditions, with various subcommittees. Local authorities and influential persons were approached and assistance offered on the lines suggested. Says the report:—

"The Italian minds were open and alert to the necessity for it (the inquiry), keen to put it into operation; the American minds, constantly having in view what was best for Italy adapted as the Italian saw it, were willing to coöperate in order to enable the Italians to secure it. The combination made a successful issue in each of the provinces chosen."

Thus, in Sardinia Mr. and Mrs. Charles W. Wright established a provincial organisation; at Palermo an anti-tuberculosis league was formed, with correlation of the work of existing organisations and extending it throughout the whole of Sicily. In the organisation the keystone was the full-time paid executive secretary, as would always be the case in similar movements in this country or in America, though in Italy the plan was practically unknown and untried. The public health nurse or visitor, who would carry the instruction given by the physicians in the dispensaries directly into the homes of the applicants for relief, was also practically unknown in Italy.

### *Schools Opened for Italian Students.*

Three schools were opened in Rome, Genoa, and Palermo, committees of Italian women being formed to act as boards of trustees, to assure the continuance of the work; only Italian students were accepted, and American nurses acted as teachers and consultants, their value being fully appreciated by the Italian physicians, and their services being completely and immediately acceptable in the homes of the people. A Section of School Hygiene was established to deal with the needs of the 3½ million children on the school registers, as well as those of an additional million not so accounted for. The birth-rate in 1914 was 31.1 per 1000; in 1916 it had dropped to 24.4; in 1918 it is considered that this ratio had fallen to somewhere between 19 and 16 for the whole country; the infantile death-rate (1910-1914) was 138 per 1000 living births; this had risen to 171 per 1000 in the large cities in 1917.

### *Housing Difficulties: An Antimalarial Campaign Wanted.*

The question of housing is considered in the report, among the special points being the size of the tenement dwellings generally occupied by the working classes in the large towns, and the difficulties presented by the numerous villages situated on hill-tops, of historic interest and picturesque charm, but hygienically presenting "so serious a problem that one wonders what the next step for Italy can be to secure an amelioration of their darkness, and dampness, and sanitary inefficiency." A long antimalarial campaign is first required. Malaria, which in 1914 had been reduced to 129,000 cases, increased during the war to 302,499 cases in 1917; and these were only the "reported cases," probably not nearly all that occurred. Pellagra has apparently not increased, but returns are not available for this disease.

### *Italian Claims for Coöperation: Practical Suggestions.*

In conclusion, the report states that Italy, "the youngest of the nations," has the following claims for full coöperation with the other nations of the world: (1) a low death-rate and high birth-rate; (2) a people who love her, no matter where they go; (3) an accomplishment as United Italy which justifies her ancient tradition; (4) as one of the greatest contributors to the labour of construction throughout the world. America owes her an especial debt, not to be paid in material things, but by fraternal coöperation. Four practical suggestions are given for carrying this out: the preparation annually in foreign languages by national and State governments of "descriptive material and charts, showing their progress in the great social movements, to be sent with the general reports for fuller reference to foreign Ministers and libraries. This method has long been used by industrial concerns in Germany, which prepare their catalogues in the language of the country in which they propose to sell, with the price quotations in the money of that country, based upon delivery at the door of the consumer. At the same time information as to international standards of public health and welfare should be

<sup>1</sup> Report of the American Red Cross Commission.

interchanged by means of a sanitary commission. Secondly, small consultative commissions, working through diplomatic channels, should secure the adoption of similar public health and welfare standards, as already has been done in regard to military and industrial affairs. A third suggestion is the establishment of international scholarships for the teaching and practice of public health and welfare work; a beginning in this direction has already been made in the scholarships offered to France by Miss E. Chalfant and Mrs. W. S. Mitchell of Pittsburgh, and the Boston French Tuberculosis Committee, also by Mr. R. B. Mellon, of Pittsburgh, who has provided three scholarships for an exchange of public health nurses between America and Italy. The value of such coöperation is undoubted, and the present instances practical proof.

#### Supplementary Reports.

To the general report above summarised, which is signed by Dr. William Charles White, the Director of the Commission, is appended a supplementary report of the Nursing Section by Mary S. Gardner, which describes the various forms of nursing that are actually in operation, and the chief points that need attention to make the service a satisfactory one according to modern requirements. To this succeeds a study of the health statistics by Mr. Knud Stouman. An excellent map of Italy shows by graduated shading the tuberculosis mortality in the various provinces of the Kingdom.

### URBAN VITAL STATISTICS.

#### VITAL STATISTICS OF LONDON DURING JULY, 1919.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 5.9 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 4.6, 4.5, and 4.7 per 1000. Among the metropolitan boroughs the lowest rates from these notified diseases were recorded in Hammersmith, Fulham, the City of Westminster, Hampstead, and the City of London; and the highest in Bethnal Green, Stepney, Southwark, Bermondsey, and Greenwich. Five cases of small-pox were notified during the month, against 7, 2, 3, and 2 in the four preceding months; of these cases 4 belonged to Woolwich and 1 to Bethnal Green. The cases of small-pox under treatment

in the Metropolitan Asylums Hospitals at the end of the month numbered 2, against 6, 1, 3, and 2 at the end of the four preceding months. The prevalence of scarlet fever was 50 per cent. more than in the preceding month, and was considerably higher than in any other month of the present or preceding year; this disease was proportionally most prevalent in Stoke Newington, Stepney, Southwark, Bermondsey, Deptford, and Greenwich. The Metropolitan Asylums Hospitals contained 1516 scarlet fever patients at the end of the month, against 1043, 1066, and 1132 at the end of the three preceding months; the weekly admissions averaged 236, against 138, 150, and 157 in the three preceding months. Diphtheria was slightly more prevalent than in the preceding month; the greatest prevalence of this disease was recorded in Hackney, Shoreditch, Bethnal Green, Southwark, Bermondsey, and Lewisham. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1134, 1086, and 1021 at the end of the three preceding months, rose to 1108 at the end of July; the weekly admissions averaged 153, against 151, 145, and 138, in the three preceding months. Enteric fever was somewhat more prevalent than in the preceding month; of the 40 cases notified during the month, 9 belonged to Woolwich, 5 to Wandsworth, 5 to Camberwell, 4 to Stepney, and 3 to Chelsea. There were 34 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 16, 19, and 25 at the end of the three preceding months; the weekly admissions averaged 5, against 2, 3, and 5 in the three preceding months. Krysipelas was proportionally most prevalent in St. Marylebone, Stoke Newington, Holborn, Bethnal Green, and Southwark. The 22 cases of puerperal fever notified during the month included 4 in Islington and 2 each in Paddington, Hackney, Poplar, and Southwark. Of the 14 cases of cerebro-spinal meningitis, 2 belonged to Fulham, 2 to Poplar, and 2 to Southwark; while of the 14 cases of poliomyelitis 2 belonged to Paddington and 2 to Camberwell.

The mortality statistics in the table relate to the deaths of civilians belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased had previously resided. During the five weeks ended August 2nd the deaths of 3801 London residents were registered, equal to an annual rate of 9.8 per 1000; in the three preceding months the rates had been 15.0, 11.1, and 9.7 per 1000. The death-rates ranged from 6.5 in Fulham, 7.8 in Lewisham, 7.9 in Stoke Newington, 8.4 in Battersea, 8.4 in Woolwich, 8.7 in Hampstead, and 8.7 in Shoreditch, to 11.1 in Southwark, 11.3 in Finsbury, 11.4 in Kensington, 11.5 in Deptford, and 12.4 in Holborn. The 3801 deaths from all causes included 154 which were referred to the principal infectious diseases; of these, 2 resulted from small-pox, 24 from measles, 14 from scarlet fever, 41 from diphtheria, 12 from whooping-cough, 6 from enteric fever, and 55 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded in Fulham and the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in the City of Westminster, St. Marylebone, Hampstead, Shoreditch, Lambeth, Wandsworth, and Lewisham; and the highest in Chelsea, Stoke Newington, Stepney, Poplar, and Camberwell. The 2 fatal cases of small-pox belonged to Woolwich. The 24 deaths from measles were one-fifth of the average number in the corresponding period of the five preceding years; of these deaths 4 belonged to Bermondsey, 4 to

#### ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JULY, 1919. (Specially compiled for THE LANCET.)

\* Including membranous croup

Camberwell, 3 to St. Pancras, 3 to Lambeth, and 2 to Wandsworth. The 14 fatal cases of scarlet fever were 3 less than the average; 3 of these belonged to Stepney. The 41 deaths from diphtheria were 10 below the average; of these deaths 7 belonged to Islington, 5 to Poplar, 4 to Camberwell, and 3 to Stepney. The 12 fatal cases of whooping-cough were one-sixth of the average number; of these, 2 belonged respectively to Hammersmith, Stepney, and Poplar. The 6 deaths from enteric fever were 4 less than the average. The 55 deaths from diarrhoea and enteritis among children under 2 years of age were 64 below the average number; the greatest proportional mortality from this disease was recorded in Hammersmith, Chelsea, Islington, Stepney, and Camberwell. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London during July was 60 per cent. below the average.

(Week ended August 16th, 1919.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 10.3, 9.7, and 9.7 in the three preceding weeks, rose to 10.0 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 10.4, or 0.9 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 3.2 in Hornsey, 3.7 in Wallasey, and 4.1 in Walsall, to 15.5 in Southport, 16.1 in Hastings, and 17.5 in Gateshead. The principal epidemic diseases caused 174 deaths, which corresponded to an annual rate of 0.5 per 1000, and included 92 from infantile diarrhoea, 35 from diphtheria, 28 from measles, 10 from whooping-cough, 5 from scarlet fever, and 4 from enteric fever. Measles caused a death-rate of 1.3 in Gateshead, 1.5 in Salford, and 1.7 in Edmonton. There were 1517 cases of scarlet fever and 1112 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1547 and 1092 respectively at the end of the previous week. The causes of 21 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham and 2 each in Gloucester and Gateshead.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 11.1, 10.5, and 10.0 in the three preceding weeks, further fell to 9.9 per 1000. The 232 deaths in Glasgow corresponded to an annual rate of 10.8 per 1000, and included 14 from infantile diarrhoea, 6 from diphtheria, 4 whooping-cough, and 1 each from enteric fever and measles. The 70 deaths in Edinburgh were also equal to a rate of 10.8 per 1000, but did not include any from the principal epidemic diseases.

**Irish Towns.**—The 111 deaths in Dublin corresponded to an annual rate of 14.3, or 1.6 per 1000 above that recorded in the previous week, and included 23 from infantile diarrhoea and 1 from measles. The 82 deaths in Belfast were equal to a rate of 10.7 per 1000, and included 6 from infantile diarrhoea and 1 from scarlet fever.

## The Services.

### ROYAL NAVAL MEDICAL SERVICE.

Surg.-Cdr. J. Chambers to be Surgeon-Captain.  
Surg.-Cdr. T. H. Vickers is placed on the Retired List at own request.  
Surg.-Capt. E. C. Lomas is placed on the Retired List.

### ARMY MEDICAL SERVICE.

Col. C. H. Melville, C.M.G., retires on retired pay.

### ROYAL ARMY MEDICAL CORPS.

Majors relinquish the acting rank of Lieutenant-Colonel on re-posting:  
A. C. H. Gray, C. R. Millar.

Major S. M. W. Meadows, D.S.O., and Major and Bt. Lieut.-Col. A. McMunn relinquish the temporary rank of Lieutenant-Colonel on re-posting.

The undermentioned relinquish the acting rank of Major: Capt. and Bt. Major R. E. Barnsley; Capt. L. J. Sheil, O. H. Brennan, R. A. Austin; Temp. Capt. W. Haward, J. V. Grant, M. R. Mackay, W. T. Hessel, Joseph S. Stewart, A. C. B. McMurtrie, R. J. Vernon, H. M. Vickers, I. Jones, L. M. Smith, G. Jackson, G. E. Nelligan, J. F. McG. Storn, T. E. Amyot, J. McDonnell, M. A. Power, L. G. McCune, C. G. McAdam, F. W. Wesley, T. Muir Crawford.

To be acting Majors: Capt. F. W. Matheson, W. E. Adam; Temp. Capt. S. Stockman, R. S. S. Statham, R. E. H. Leach, P. P. J. Stewart, C. E. Walker.

Capt. G. D. Robertson resigns his commission.  
Capt. N. T. Whitehead relinquishes the acting rank of Lieutenant-Colonel on ceasing to command a Medical Unit.

Capt. D. H. C. MacArthur relinquishes the acting rank of Major.  
Capt. R. H. Graham, from Spec. Res., to be Captain.  
Temporary Captains to be Captains: R. N. Porritt, A. R. Oram.

Captains from the T.F. to be Captains: G. F. Carr, C. M. Gozney.  
Temporary Lieutenants to be temporary Captains: J. Paxton, V. D. Pennefather, G. S. Livingston, N. B. Benjafield, J. McClellan, A. P. Mitchell, G. H. Dart, J. C. Warwick, E. H. Milson, A. E. Hodgkins.

Capt. A. G. Harsant, from Spec. Res., to be Lieutenant, and to be temporary Captain.

Temp. Lieut. J. E. Rea to be Lieutenant.  
Officers relinquish their commissions:—Temp. Lieut.-Cols. (retaining the rank of Lieutenant-Colonel) E. W. Goodall, W. D. Buncombe, F. S. Toogood, A. D. Reid, H. L. Eason; Temp. Hon. Major G. Hodge (retains the honorary rank of Major); Temp. Major and Brevet Lieut.-Col. A. W. Robinson (retains the rank of Brevet Lieutenant-Colonel); Temp. Majors (retaining the rank of Major) G. H. Ross, T. MacKenzie; Temp. Capt. and Brevet Majors (retaining the rank of Brevet Major) W. S. Stalker, E. C. Williams, R. McC. Hill; Temporary Captains granted the rank of Major: D. D. Craig, W. B. Davy, J. R. M. Whigham, A. W. Uloth, A. K. H. Pollock, A. E.

Marsack, J. W. Littlejohn, F. W. Wesley; Temporary Captains retaining the rank of Captain: J. Scott, R. W. Valentine, H. L. Morrow, R. T. Stoney, T. F. S. Fulton, J. H. Wilks, T. Brodie, C. Brash, D. McCormack, J. S. Annandale, B. L. Livingstone-Learnmouth, J. M. Woyte, J. E. M. Wigley, P. A. Creux, S. H. L. Archer, S. E. Murray, R. H. S. Marshall, P. J. Kelly, J. C. D. Allan, L. H. Leeson, B. F. Macnaughton, F. R. Hassard, D. Whyte, S. Y. Walsh, W. A. Proud, G. R. Bickerstaff, A. W. Adams, E. G. Fenton, J. M. Wishart, W. B. A. Moore, H. W. Crowe, J. M. Gibson, D. MacGregor, J. C. Hindley, J. Patrick, L. Zealand, F. F. Carr-Harris, C. G. Winter, J. S. Stewart, D. H. Paul, R. F. Wilkinson, A. G. Gilchrist, C. W. Smith, G. Matthews, D. F. A. Neilson, R. W. Smith, A. B. Raffle, J. H. Wrightson, E. Duke, A. M. Clare, R. A. Flynn, E. Billing, A. Brown, C. W. Fowler, F. H. Diggle, P. N. Vellacont, B. G. Gutteridge, J. R. Marrack, H. W. Parnis, J. F. Carroll, C. H. Ayles, G. O. Grain, C. E. Bashall, A. G. Neismitb, O. H. Bowen, B. T. Parsons-Smith, G. M. C. Powell, L. P. Booth; Temp. Hon. Capt. J. B. Fearn (retains the honorary rank of Captain); Temporary Lieutenants retaining the rank of Captain: W. A. Mein, L. H. McConnell, D. R. Wheeler, W. Gilmore.

### Canadian Army Medical Corps.

Temp. Major (acting Lieut.-Col.) E. L. Pope to be temporary Lieutenant Colonel.

Temporary Captains (acting Majors) relinquishing the acting rank of Major: N. W. Strong, W. E. Gallie.

The undermentioned temporary Captains retire in the British Isles:—W. B. Honey, C. V. Bailey, T. V. Hunter, H. J. Thierault, J. A. MacKenzie, J. A. Jardine, J. R. Le Touzel, W. A. Marshall, P. A. Leacy, W. H. Hills, C. V. Mills, M. R. Boe, H. H. Perry.

### Canadian Army Dental Corps.

Temp. Capt. B. E. Brownlee retires in the British Isles.

### SPECIAL RESERVE OF OFFICERS.

Capt. J. P. Charnock relinquishes the acting rank of Major.

Capt. O. Williams to be acting Major.

Capt. A. C. Irvine relinquishes his commission.

Lieutenants to be Captains: M. Jackson, G. P. W. Staunton, T. H. Almond, J. N. Gele, J. W. Mann, F. K. Escrib, A. C. Paterson, A. E. B. Paul.

### TERRITORIAL FORCE.

Lieut.-Col. (acting Col.) F. W. Higgs relinquishes the acting rank of Colonel on vacating the appointment of Assistant Director of Medical Services.

Lieut.-Col. G. C. Taylor vacates the appointment of Deputy Assistant Director of Medical Services.

Lieut.-Col. R. Emmett relinquishes his commission on account of ill-health, and retains the rank of Lieutenant-Colonel.

Capt. (acting Majors) relinquishing the acting rank of Major on ceasing to be specially employed: C. S. Wink, C. M. Nicol, J. Anderson, W. E. Lee, J. Ramsay, J. Turle, A. Wilson, D. G. Kennard, H. S. Wallace, A. J. A. McC. Dallas, P. J. Smyth.

Capt. (acting Major) M. B. G. Sinnott relinquishes the acting rank of Major on vacating the appointment of Deputy Assistant Director of Medical Services.

To be acting Majors while specially employed: Capt. C. E. Whitehead, A. M. Jones, C. M. Nicol.

Capt. W. J. Hoyten relinquishes his commission on account of ill-health, and is granted the rank of Major.

Capt. S. A. McPhee relinquishes his commission on account of ill-health contracted on active service, and retains the rank of Captain.

4th London General Hospital: Lieut.-Col. A. H. Tubby is restored to the establishment.

1st Scottish General Hospital: Major H. Mc I. W. Gray is restored to the establishment on ceasing to hold a temporary commission in the Army Medical Service.

2nd Scottish General Hospital: Capt. J. W. Simpson is restored to the establishment.

2nd Western General Hospital: Capt. (acting Major) G. M. Benton relinquishes the acting rank of Major on ceasing to be specially employed.

2nd London Sanitary Company: Capt. B. R. Hebblethwaite is seconded for service under the Egyptian Government.

### ROYAL AIR FORCE.

**Medical Branch.**—Major (acting Lieut.-Col.) B. R. Bickford, D.S.O. (Staff Surgeon, R.N.), relinquishes his commission on ceasing to be employed.

The undermentioned are transferred to unemployed list: Major C. F. Bainbridge, Capt. K. B. Aickman, R. Hall, Lieut. N. Homewood. Capt. T. E. Mulvaney relinquishes his commission on account of ill-health contracted on active service, and is permitted to retain his rank.

Lieutenants to be Captains: C. T. Costello, G. M. Mellor, H. C. Cox, G. Meadows, L. C. Broughton-Head, H. B. Troup, H. T. Fry-Jones, J. Coulter-Smith, R. Munglison, P. E. Williams, C. Lambird, A. Kirkhope, P. M. Carroll, J. P. Horsford, A. K. Soutar, G. Dunderdale, J. P. Hennessy, G. W. Harbottle, M. J. Wblton, J. Valerie, J. P. Wells, A. St. J. Hennessy, G. W. J. Bonsfield.

**Dental Branch.**—Lieutenants to be Captains: G. Warner, R. Fyson, C. M. Shirreff, H. L. Thorn, N. H. Medhurst, N. L. Smallbone, C. M. John, G. Hughes, G. F. H. Bloom.

### INDIAN MEDICAL SERVICE.

Captains to be Majors: V. B. Green-Armstrong, A. N. Dickson, A. G. Coullie, A. J. H. Russell, Dewan Hakumat Rai, W. H. Riddell.

Lieutenants to be Captains: J. P. Huban, Erach Ruttanji Daboo, M. M. Cruickshank, Anant Yashwant Dabholkar, Kekhasra Sorabji Master, S. A. McSwiney.

Temporary Lieutenants to be temporary Captains: Har Sukh Raj, Nawab-ud-Din, M. J. Saldanha, Yeshwant Vaman Modak, Ragavan Chervuraji Toyle, Abdul Kadir Muhammad Mahiuddin, A. Noble, Joy Devananda Sinha, Dinesh Chandra Chakrabarti, Ravu Venkata Rao, Annaswamy Mutbnukrishnan, Sadashiva Chintaman Lele, Jagdish Chandra Gupta, Colmbatore Srinivasa Rao Venkata Krishna Rao.

The following officers are permitted to retain the temporary rank of Captain on permanent appointment as Lieutenants: Durgadas Sanyal, Fazal-ud-Din, Girish Chandra Maitra, Bijitendra Basu, Sankaranai-narkoil Chidambaranatha Alagappan.

The King has approved the appointment of the undermentioned Lieutenants permanently to the Indian Medical Service: John Patrick Huban, Erach Rutnanji Daboo, Martin Melvin Cruickshank, R.A.M.C. (T.C.), Anant Yashwant Dabholkar, I.M.S. (T.C.), Kekhasru Sorabji Master, I.M.S. (T.C.), Stephen Alphonous McSwiney, R.A.M.C. (T.C.), Durgadas Sanyal, I.M.S. (T.C.), Fazal-ud-Din, I.M.S. (T.C.), Girish Chandra Maitra, I.M.S. (T.C.), Bijitendra Basu, I.M.S. (T.C.), Sankaranainarkoil Chidambaranatha Alagappan, I.M.S. (T.C.).

*Indian Defence Force.*—Lieutenant to be Captain: J. S. Nicolson.  
The King has approved the relinquishment of temporary rank in the Indian Medical Service and Indian Defence Force by Captain A. MacL. Ramsay.

#### HEALTH OF TROOPS ON AFGHAN FRONTIER.

The Secretary of State for India, in a written answer to a question by Colonel Yate concerning the arrangements made for the health and comfort of the troops on the North-West Frontier of India, denies the reports of deficiencies in the Afghan campaign. Quoting from a telegraphic report, he says that with regard to food, &c., two essentials at this time of the year are ice and mineral waters. Ice-machines are working at the following places: Rawal Pindi, Nowshera, Peshawar, Kohat, Bannu, Dardoni, Tank, Dera Ismail Khan, and Quetta, and further machines are under erection. As regards soda-water machines, 22 are already working on the frontier and six more are on their way to the frontier. The total daily output of these machines will be approximately 90,000 bottles. This output is in addition to that of local factories. Each machine is being sent up complete with cylinders and bottles for one month's consumption, and a reserve of three months has been arranged for. Mineral waters are issued to all officers and men in hospital. The scale of rations for British and Indian troops is much superior to any previously granted for campaigns in India. Under the new scale for Indian troops the meat ration has been doubled and a daily issue of fresh vegetables, condensed milk, as well as weekly issues of cigarettes, provided. Orders have been issued to all generals in command that medical officers are to ask for whatever they deem necessary for the comfort of the sick and wounded in their charge and that their demands are to be met at once. Additional hospitals for 4000 British and 8000 Indian troops have been established in specially fitted barracks in proximity to the frontier, and electric lighting and fans, where none already exist, are being supplied to the former. Convalescent depôts for officers and soldiers have, in addition, been formed, mainly in the Murree hills. Special arrangements have been made for the supply of fresh milk to the sick. Arrangements for providing additional equipment are in progress, and have been made already for the establishment of field force canteens for British and Indian troops. Special messes have been formed at various places for the use of individual officers passing through. Rest camps for British and Indian troops en route to the front have also been organised. To ensure that the arrangements for the health and comfort of the troops are working satisfactorily and up to the standard designed by the Commander-in-Chief in India, staff officers from general headquarters carry out under his Excellency's orders frequent tours of inspection on the frontier. Specific inquiry is being made into each definite allegation of deficiency that is brought to notice.

## Medical News.

**ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.**—An extraordinary meeting of the College was held on August 8th, Sir Robert Philip, the President, in the chair. H.R.H. the Prince of Wales having signified his willingness to accept the Honorary Fellowship of the College, was elected by acclamation.

**ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.**—At the Conjoint Examinations held recently the following candidates were successful:—

#### THIRD PROFESSIONAL EXAMINATION.

H. C. Bell, Miss L. H. Byrne, J. F. J. Cleary, R. H. Dolan, M. A. English, J. Fitzsimons, J. J. Fitzsimons (honours), Mrs. M. W. Frazer, T. P. Hefferman, T. E. Kavanagh, Miss A. Ledlie, J. I. Levi, J. J. McHenry, Miss M. G. Neill, Miss I. P. Nelis, Miss M. C. O'Brien, R. C. Ogden, J. O'Leary, J. J. O'Sullivan, P. J. Quigley, T. J. Ryan, W. H. Sexton, R. B. Shaw, J. Tahan (honours), J. W. Tighe, A. D. Watchman, and T. G. Whitcroft.

#### FINAL PROFESSIONAL EXAMINATION.

Michael Barden, Baron Asher Cowan, Joseph Cockburn, Thomas Coffey, Robert Stafford Conyngham, John Francis Gallagher, Daniel Hegarty, Alexander Francis Mallon, John Patrick Morgan, Bernard Thomas McMahon, James McAlister, Michael Joseph O'Connor, Frank Gaed Phillips, Joseph Power, Joshua Ponsner, Andrew Thomas Rathigan, Thomas Kerry Reddin, and William Edward Shipsey.

#### DIPLOMA OF PUBLIC HEALTH.

Patrick Ashe, Geoffrey Collins, Ignatius B. Culhane, Edmund W. Lynch, John D. MacCormack, S. D. G. McEntire, C. C. Macredy, Lionel M. Rowlette, and J. R. Bibby.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—At examinations held recently the following candidates were successful:—

#### PRIMARY FELLOWSHIP EXAMINATION.

Robert H. L. M. Corbet, W. J. Corkey, Mary G. Hogan (honours), and Eric S. Horgan.

#### FINAL FELLOWSHIP EXAMINATION.

W. H. W. C. Carden, J. V. Cope, and J. A. Fretton.

As we announced last week, the League of Red Cross Societies have appointed an International Commission to investigate the public health conditions in Poland, with a special view to providing against the spread of typhus and other epidemics across Western Europe. Dr. Addison, the Minister of Health, has lent to the International Commission the services of Dr. G. S. Buchanan, the other members of the Commission being: for Italy, Professor Castellani; for the United States, Colonel H. Cumming; and for France, Lieutenant-Colonel Visbecq, of the Service de Santé of the French Army, the last in place of Monsieur E. Dopter, who has been prevented from starting for Poland.

**EASTBOURNE AND CHILD WELFARE.**—The members of the corporation of Eastbourne are far-seeing, and without opposition have voted no less a sum than £4500 for maternity and child welfare purposes. A home where the work has been carried on some time voluntarily has closed through lack of funds, and the corporation has stepped into the void. The scheme is being pushed on as the need is urgent owing to the house famine. Eastbourne is thus doing its part in the great work of conserving child life, the necessity for which has never been brought home so much as it is to-day.

**MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.**—A committee meeting of this society was held at 300, High Holborn on August 15th, when the accounts presented showed that influenza had practically disappeared in the claims for insurance. The volume of new business continues to be exceptionally good, but an increasing number of medical men appear to be retiring from practice at a comparatively early age, necessitating increased new business in maintaining the total membership. The claims are under the expectation for the month, but signs are not wanting that the strain on older members of the society during the last years is beginning to show, long rest from all work being then compulsory. This is essentially the kind of claim that proves the value of the society's sickness contract, for in many policies the benefit only lasts a certain time, while the society goes on paying for years if required.

All particulars may be had from the Secretary, Medical Sickness and Accident Society, 300, High Holborn, W.C. 1.

**ROYAL MEDICAL BENEVOLENT FUND.**—At the last meeting of the committee, held on August 12th, 30 cases were considered and £308 10s. voted to 27 of the applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 47, of M.D. Lond. who practised in London and died in 1873. Lives with two elder sisters, one of whom receives help from the Fund. Has £15 per annum from dividends. Asked to take in pupils, but now wishes to commence a school, and she asks for help towards books, stationery, &c. Voted £12 10s.—M.R.C.S. Eng., aged 44, who practised at Theale. Was in a serious motor accident in June, 1918, and is still suffering from head injury and loss of memory and is quite unable to work, and has had to sell his practice. Receives £24 pension from workhouse and £6 6s. a month from the Medical Sickness Society. Rent and rates £37 13s. 6d. Has three children; the eldest girl is at home and the other two children are at school. Voted £50.—Widow, aged 47, of F.R.C.S. Edin. who practised in London and died in February, 1919. Was left totally unprovided for, and is now acting as a temporary clerk at 37s. 6d. a week. Lives in one room and pays 8s. a week rent. Applicant's husband was helped by the Fund. Voted £5.—Widow, aged 53, of M.B. C.M. Aberd. who practised in London and died in 1917. Was left without means. Has three children; the two eldest are in the Army and both have been wounded, and the youngest is still in the hospital waiting to undergo an operation. She receives £62 a year from children and £26 from the Pensions Committee. Pays £26 a year rent. Voted £12 in 12 instalments.—Widow, aged 60, of L.R.C.P. Edin. who practised at Blackburn and died in 1902. Is at present doing domestic work at 9s. a week, but she suffers from ill-health and cannot stay long at any post. Was in the infirmary for a greater part of last summer. Has one daughter who acts as a children's nurse and receives £26 a year. Relieved six times, £30. Voted £12 in 12 instalments.—Daughter, aged 61, of L.F.P.S. Glasg. who practised at Lauchline, Ayrshire, and died in 1883. Is unable to work owing to ill-health. Only income £15 from the Scottish Indigent Women's Fund. Pays £10 a year rent. Relieved 11 times, £116. Voted £18 in 12 instalments.—Daughter, aged 38, of M.D. Dub. who practised at Moorcroft, British Guiana, and died in 1884. Lives with her mother, who receives a pension of £50 per annum. Suffers from ill-health and is unable to earn her own living. Relieved 13 times, £120. Voted £10 in two instalments.—Widow, aged 63, of L.R.C.P. & S. Glasg. who practised at Walsall and died in 1902. Was left unprovided for with two children, who are now working and pay their mother £1 a week each, and applicant receives about £12 a year by needlework. Relieved 13 times, £142. Voted £5.—Daughter, aged 68, of M.R.C.S. Eng. who practised at Liverpool and died in 1881. Receives £6 a year from dividends and £52 a year from friends. Lost all her money through the failure of an Australian bank. Suffers from ill-health. Relieved six times, £72. Voted £12 in 12 instalments.—Widow, aged 51, of L.S.A. Lond. who practised at Plaistow and died in 1911. Was left with two children, now aged 16 and 14. The elder one wishes to train for a nurse; the younger is still at school. Applicant receives £100 a year from the sale of the practice and from late husband's life insurance, and has to pay £27 a year rent. Asks for help owing to increased cost of living. Relieved twice, £17. Voted £5.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W. 1.

"Audi alteram partem."

## THE NEED FOR ACCESSORY FOOD FACTORS IN INFANT FEEDING.

To the Editor of THE LANCET.

SIR,—The appalling loss of life which occurred during the war brought into prominence for the first time the need for economy in life generally, and more especially that of infants. The survival of the less fit may be eugenically wrong, but so often infant life depends not on fitness to survive so much as in the knowledge and fitness of the mother. And so there came into being the vast organisation of infant welfare centres throughout the country and the initiation of schemes for ensuring adequate nourishment and care to growing infants. In London the raids put many nursing mothers off their milk, especially in the areas severely visited, and this at a time when the scarcity of cow's milk was keenly felt, and when whole districts were without adequate supply. Then it was that the Government wisely encouraged the use of dried milk, and an exhaustive report on dried milk was made to the Local Government Board. It was shown that the absence or destruction of antiscorbutic factor in the dried milk had no apparent influence on the children's growth, nor did Barlow's disease appear save in very exceptional cases. There is no doubt that animals suffer from the deprivation of the antiscorbutic vitamin in their food much more rapidly and severely than does the human infant. The reason for this is not known. Whether the mother is able to transmit a tolerance in her infant to a vitaminless diet, or whether the human young require much less than do animals to keep them in health is pure speculation, but the probability is that when infantile scurvy has advanced to the stage of physical signs we have arrived at the last chapter of the disease, not the first. Zilva has shown that the growing teeth of the guinea-pig are very early affected by the absence of vitamin in the diet, and there is reason to suppose that the cause of some of the ailing, without actual disease, of infants is caused by the absence of vitamin. So far we have no knowledge of the influence of such absence on the early growth of the permanent teeth. At University College Hospital it has long been felt that it was not right wilfully to withdraw this vitamin from the diet of these artificially fed infants, even although no very obvious symptoms of scurvy had been encountered, and Dr. Harriette Chick suggested two years ago the use of an apple jelly the vitamin in which was not destroyed in the process of manufacture. This jelly was made for the Army, and, alas, is now unobtainable. It did not disagree, and was quite palatable. As the manufacture was discontinued, orange-juice has been used, and successfully, and is well tolerated by even the youngest infants. The rind is mixed with the pulp, as the essential oil, present only in the rind, preserves the juice for quite a long period. The minced orange is then squeezed through a tincture press and the juice collected. The doses given are a teaspoonful in a little sugared water twice daily under three months, and double that amount over that age.

As to the fat-soluble A factor, this is present in the dried milk in sufficient quantity to prevent rickets, but where in some cases the infant does not tolerate dried milk and diluted cow's milk has to be substituted the dilution of the cow's milk becomes an anxiety unless cream is added to the feed. Cream is unobtainable or prohibitive, and as the Marylebone cream is useless so far as fat-soluble is concerned a cream has been in use for many months at the Infant Department at University College Hospital made of beef suet, which is rich in fat-soluble. This cream has a richness in fat equal to ordinary skimmed cream, cannot go bad, and is dispensed at a very low cost. The conversion of suet into an emulsion miscible with all dilutions of milk was found to be difficult by reason of the high melting point of suet. This was overcome at last, and the method of manufacture and the formula (I quote from a paper by Mr. Hampshire and Mr. Hawker in Transactions of the British Pharmaceutical Conference, 1919) are as follows:—

Beef suet, 40 oz.; olive oil, 5 oz.; syrup, 25 fl. oz.; benzoic acid, 35 gr.; decoction of Irish moss, 70 fl. oz.; water to 1 gallon. "The oil is added to the melted suet and the benzoic acid dissolved in the mixture. The decoction is

heated to about 60° C. and placed in the emulsifier, and the fats are then added at about the same temperature. The emulsion is then worked up and the syrup and water added last." I am, Sir, yours faithfully,

E. A. BARTON,  
Medical Officer to Infant Department,  
University College Hospital.

August 14th, 1919.

## THE INCIDENCE OF TUBERCULOSIS AMONGST ASYLUM PATIENTS.

To the Editor of THE LANCET.

SIR,—The paper by Dr. F. A. Elkins and Dr. Hyslop Thomson in your issue of August 9th brings forward many interesting points, to me none more so than the paragraph on clinical features, in which they insist on the extraordinary absence of the classical symptoms and signs of pulmonary tubercle which obtains in the asylum phthisical patient. This is, of course, a fact that is perfectly well known to those of us who have spent some time resident in institutions for the care of the insane, but it is, I find, not appreciated by those who have not, and it is important that it should be more widely known because, for one thing, large numbers of the more chronic insane are still under treatment in the union wards, where the resident or other medical officers are often of a temporary character, or, even if this is not the case, are not so *au fait* with these matters as the expert alienist.

My experience as medical officer in charge of the Western Command Epileptic Centre at the Nell Lane Military Hospital, where for the last two years of the war we have had 68 beds occupied by epileptic soldiers under careful observation, does not lead me to include epileptics under the heading of those predisposed to tubercle; these were, with few exceptions, sane epileptics, but we were struck with the small incidence of tubercle amongst them, smaller indeed, by a good deal, than the average incidence of tubercle amongst medical military patients as a whole.

I do not altogether agree with Dr. Elkins and Dr. Thomson in ascribing so much importance to contact infection when seeking for explanations of the war-time increase in asylum tubercle. To my mind, most of these patients had a latent focus of tubercle on admission, and owing to the poor food, the war-time rationed deficiency of fats, sugar, &c., the resistance was diminished so that the dormant focus became active again. Those who have made post-mortems at all frequently on the asylum type of patient know well that scars of healed apical tubercle are met with in the vast majority of these bodies, and it is casting no stigma on the asylum medical officer to suggest that on admission a far greater number were suffering from tubercle than are so recorded in the table given. His duties on the admission of a patient are to examine that patient and to fill up forms concerning him; he is especially interested in the mental condition, and it is not to be expected that he is likely to spot doubtful or latent foci in the lungs in the way that a tuberculosis specialist would.

"It is true that insane tuberculous patients have rarely any expectoration, and therefore the medium of infection is obviously not sputum." This seems to be going rather too far, both as regards reinfection in the bowel of the patient himself and infection of others in the same ward. In the insane phthisical patient the cough is absent, and sputum, in the strict sense of the word, is also absent, but the morbid material and secretion from the air passages is produced, and reaches the oro-pharyngeal cavity in some, though it may be in small, quantity, and is doubtless swallowed, constituting a medium of contact infection. In addition to this, the contents of the mouth and pharynx may be, as is well known, disseminated through the air for many feet—in the absence of coughing—by speaking, sneezing, or even by the snoring and stertorous breathing of so many of these cases, and such morbid material, being present in the mouth, may contaminate spoons, forks, and drinking vessels, hence infecting others if the washing arrangements are at all perfunctory. The same absence of cough and sputum, the same laryngeal anaesthesia, occur also in the deglutition pneumonia and pulmonary gangrene of asylum patients, another common cause of an insane patient's rapid decline, which has in these subjects the same insidious onset as pulmonary tubercle has.

The authors of the paper ascribe the transference of disease to infected hands and bedclothes. I believe this

holds good, to some extent, as far as the patient himself is concerned, but I do not think, in a well-ordered asylum, that the infection extends to those in neighbouring beds, where I think the natural predisposition of the mental case to tubercle or the lighting up of an old focus plus the diminished resistance from war-time poverty of rations will explain everything not explained by aerial transmission of mouth contents and possibly by contaminated eating and drinking utensils.

I agree entirely as to the importance of cubic space and ventilation. In asylum hospital wards it is often the case that too little air space is allowed for the case of acute infection. It is often also a fact that asylum ward ventilation is poor, given sufficient air space, owing to the bottoms of the windows being for other reasons at a higher level than usual from the floor. Tubercle in the insane is hopeless; in them "early or suspected cases" are in reality too advanced for any treatment to arrest the disease.

I am, Sir, yours faithfully,

FRANK E. TYLECOTE, M.D., D.P.H., M.R.C.P.,  
Assistant Physician, Manchester Royal Infirmary; Visiting  
Physician to the South Manchester Union Hospitals and  
Lunacy Wards; sometime A.M.O. and Pathologist,  
Winwick Asylum.

Manchester, August 12th, 1919.

To the Editor of THE LANCET.

SIR,—I do not think that Dr. F. A. Elkins and Dr. Hyslop Thomson, in their paper published in THE LANCET of August 9th, lay enough stress on the importance of ventilation in asylums when writing on the incidence of tuberculosis. In my opinion the bed-space requirements of the Board of Control (50 square feet in ordinary wards and 67 in hospital wards) is quite inadequate for an asylum population. It must be borne in mind that even for a large asylum they only recommend an isolation hospital with three beds for each sex, which quite precludes the treatment of colitis, for instance, in such hospital. Some years ago I saw at Shrewsbury Asylum what I thought was an admirable arrangement for ventilation, especially in hot weather. The lower sash of each window was of double length, the lower half being unglazed and being housed below the window-sill when the window was closed; when raised it had the effect of a widely open window, the empty frames fulfilling the purpose of bars without their appearance. I suggested the adoption of this arrangement in a new asylum some years ago, but the Commissioner to whom my suggestion was referred poochpooed it.

As regards the dietetic requirements, I do not think that any asylum superintendent would deny that the excessive mortality from tuberculosis since 1914 was due to insufficient food, and that it would have been much greater if the requirements of the Board of Control (no doubt under the direction of the Food Controller) had been carried out literally.—I am, Sir, yours faithfully,

H. K. ABBOTT,

Medical Superintendent, Hants County Asylum,  
August 18th, 1919. Knowle, Fareham.

## THE RESULTS OF COMPLETE COLECTOMY.

To the Editor of THE LANCET.

SIR,—Under the above heading Mr. J. F. Dobson criticises, I think with justice, the imperfect manner in which Major James Taylor has recorded his series of six total colectomies in THE LANCET of August 2nd. Apparently Major Taylor is a whole-hearted disciple of Sir Arbuthnot Lane, and he carries his intimation so far as to imagine that his readers will be satisfied with the statement that the patients made an excellent recovery from the operation; that he has seen four of his cases recently, of whom three were not troubled with looseness of the bowels.

My own experience of total colectomy is limited to one case, and I freely admit that only a few days ago the patient consulted me on account of disturbed nights owing to looseness of the bowels. The colon in this case was excised for dilatation and recurrent attacks of obstruction. Her symptoms are markedly improved, and her looks are satisfactory, but she is not yet free from intestinal troubles.

It appears to me high time for a clinical demonstration of these cases of complete colectomy, and I hope that steps may be taken in this direction at the Surgical Section of the Royal Society of Medicine. We must be supplied with scientific data on this subject, and the matter should no longer be obscured by such literature as is provided in Sir Arbuthnot

Lane's book, entitled "The Operative Treatment of Chronic Intestinal Stasis"; a rather quarrelsome symposium by several authors, abounding both in contradictions and repetitions. This has been adequately reviewed in the April number of the *British Journal of Surgery*, and apparently the art of "slating" is not quite a lost one.

The pity of it is that such a straightforward surgical question should not receive a clear answer. If the whole colon should be removed by all means let us resect it, not because we can, but because we ought.

I am, Sir, yours faithfully,

Devonshire-place, W., August 14th, 1919. JOSEPH E. ADAMS.

## A CRITICISM OF THE MEMORANDUM ON MALARIA.

To the Editor of THE LANCET.

SIR,—May I offer one more criticism of the Memorandum on Malaria recently issued by the Ministry of Pensions? The object of such a publication is, I imagine, to give help to the civil practitioner when called upon to diagnose and treat cases of malaria that have been discharged from the Army, but the vague instructions and information that it gives must, I feel sure, mislead rather than guide him.

*Description of the Forms of Malaria.*

The diagnosis as described is correct, but it deals almost exclusively with the features of what I call a true tropical attack. When demobilised and sent home to England, cases often show symptoms of a far different nature, their condition being post malarial, and post malarial conditions are essentially influenced by climatic and hygienic conditions. The practitioner will, in all probability, be called to treat cases confined largely to the following classes: 1. Those who have already been through a thorough course of hospital treatment following the acute attack—and the vitality of the infecting plasmodium therefore reduced. 2. Those who have already become reacclimatised to home conditions.

Cases such as these will not give symptoms of true tropical attacks. It is the subsequent general constitutional disturbances that will make for difficulty of diagnosis. There will be every kind of obscure symptoms, and men without knowledge of these, whilst looking for the standard symptoms, will probably fail even to recognise them. Therefore the Memorandum should have laid special emphasis on the symptoms and appearances of post tertian and quartan cases, as it is highly improbable that men suffering from the more severe forms would be discharged and sent home.

The Memorandum makes a strong point of "periodic attacks," but this, I think, is misleading; it should only arouse suspicion; it should surely never make diagnosis certain. Many chronic cases never show a typical rigor. Enlargement of the spleen is mentioned as being important; this is correct, but no word is spoken as to the character of enlargement—i.e., the recent case giving "soft" and the long and chronic case giving the "hard" (ague cake)—two conditions requiring entirely different treatment. Pigmentation of various degree, especially around the eye, jaundice, the cold clammy skin with sweating head and tachycardia—these I have seen as giving the only symptoms of undoubted malarial cases. Fine muscular tremors, with anæmia and emaciation, likewise, are the only symptoms of another group of cases.

Nervous disorders should have been given a very important place. Peripheral neuritis, muscular and auditory hyper- and an-algesia, vertigo, and impotence should all have been laid stress upon. "Severe symptoms are usually absent," so says the Memorandum, but surely many of the conditions I have mentioned may be most serious, and nephritis, which is often present, especially so.

Under the vague term "malarial cachexia" a countless number of important symptoms are summarily dismissed. Diagnosis by aid of the blood film is good in the hands of an expert, but almost impossible to the practitioner. A great amount of patience and quite a fair amount of experience is necessary, and no mention is made of the very important fact that a blood film taken within 24 hours of a patient being given large doses of quinine is almost valueless. Films taken between attacks often give negative results. The best time to take the blood is about ten hours after the rigor. In brief, instead of diagnosis being a simple thing, as the

Memorandum assumes, except in acute cases, it may be extremely difficult.

#### Treatment.

I agree with Dr. Gordon Ward that the general and indiscriminate administration of quinine is not sound advice. Quinine is the standby in acute cases—given a few hours before or during sporulation (i.e., the attack) and for some time afterwards—but to give this drug for several months on end to chronic anæmic and emaciated non-febrile cases is folly. A man must “know” quinine and understand malaria. Dr. T. H. Jamieson, in his letter of August 9th, makes the same mistake as the Memorandum. He speaks as if there were but one type of case to consider. The cessation of rigors by the action of quinine does not mean that there has been any cure of malaria. To the civil practitioner this above all things should be pointed out to him—viz., that for any length of time after the attack is cured later symptoms may, and probably will, develop, and that when these later symptoms follow quinine is to be avoided. The administration of a powerful protoplasmic, and therefore metabolic, poison to a person whose natural bodily resistance has already been lowered by the infection, is obviously a practice to be condemned. The danger we have to fight against is not the one Dr. Jamieson suggests—i.e., the failure to give adequate doses of quinine for a sufficiently long period—but the very opposite; the failure to discontinue quinine in cases of malaria showing a post-malarial condition. Dr. Jamieson's statement that such a condition—i.e., “chronic tachycardia and effort syndrome”—“is in most cases the result of inadequate doses of quinine for a short period” shows merely an attempt to substitute fancy for fact. I have suffered myself from the effects of malarial infection for the last ten years—I have undergone thorough hospital treatment with quinine in full doses for some time. I have been cured of the attacks, but no amount of quinine could have prevented my present post-malarial symptoms from developing, and it is because my experience has taught me to avoid quinine now that I am able to enjoy comparatively good health. It is the post-malarial conditions that will be met with mostly in this country, and for these the iron salts with arsenic, colloid preparations of iodides, organotherapy, high frequency, &c., all find their legitimate use.

I have had a varied and extensive practical experience, extending over ten years in the native and European hospitals in Africa (and more recently in the last campaign), and I know that the civil practitioner at home here will, if he adheres to the principles laid down in the Memorandum and Dr. Jamieson's letter, find much to perplex and deceive him.

I am, Sir, yours faithfully,

C. R. CORFIELD, B.Sc., L.M.S.S.A.,

Late Superintendent, Govt. Area and Glencalrn Hospitals,  
August 16th, 1919. Transvaal, South Africa.

#### To the Editor of THE LANCET.

SIR,—In your issue of August 9th Dr. T. H. Jamieson takes me to task for what he describes as “pernicious and dangerous advice.” May I be permitted a few words in reply? Dr. Jamieson seems to assume that I habitually give smaller doses of quinine than he considers correct. As a matter of fact, I give the same doses as he does himself; nor is there anything in my previous letter to suggest that I ever did otherwise. I plead guilty, however, to calling attention to the fact that there is something more than quinine administration to be thought of—i.e., “improvement of the natural resistance of the body.” Anyone who was able to judge of the results obtained by hospital and convalescent camp treatment respectively, the quinine dosage being the same, must bear me out in this. I gather that Dr. Jamieson has not had the opportunity of studying this experiment—for as such it may be regarded—which was so successful with the 10th Division on their return from the East to France. This same experiment also goes far to disprove Dr. Jamieson's assertion that effort syndrome is commonly due to insufficient or irregular quinine treatment, inasmuch as the effort syndrome, &c., persisted in hospital but disappeared in convalescent camps.

I stated that the instructions about intramuscular injection in the Memorandum were unwise. I still think so. Dr. Jamieson says that “a very elementary knowledge of anatomy will enable one not to inject in the close proximity of an important nerve trunk.” So it will, but this elementary knowledge is not always available, as witness the fact that

the official instructions on this matter issued to M.O.'s of the Salonika army were grossly inaccurate as to the position of structures in the buttock.

Dr. Jamieson speaks as if he believed that quinine killed the malaria parasite and that no other treatment was necessary. This view has been widely held, but I recently had the pleasure of hearing Sir Ronald Ross admit publicly that he had grave doubts whether quinine had any direct effect at all on the parasite—a conclusion to which many others have come. In the circumstances blind reliance on quinine ought not to constitute the whole therapy of the disease, as was usually the case in military hospitals.

In conclusion, may I say that the Medical Society of London is holding a discussion on the treatment of malaria on Nov. 24th. I should feel honoured if Dr. Jamieson would be my guest on that occasion, if he has not had an invitation from other sources. He may rest assured that I may be “pernicious,” but I am not “dangerous,” so that he can accept with safety.

I am, Sir, yours faithfully,

Sevenoaks, Kent, August 18th, 1919.

GORDON WARD.

## THE CONDUCT OF LABOUR AND PUERPERAL SEPSIS.

### To the Editor of THE LANCET.

SIR,—Dr. J. H. E. Brock, discussing in your columns last week an aspect of puerperal sepsis which has been neglected for some years, would have us believe that “the reason why there is such a large amount of sepsis still rampant in parturition is that the woman begins her labour with the vaginal canal, and sometimes the uterine canal, surgically unclean,” and that the sepsis is due to the inoculation, by the examining finger, of the cervix and uterine wall with organisms introduced into the vagina during sexual intercourse. I think it can be shown that Dr. Brock has over-estimated the danger of intercourse during pregnancy, and I should like to suggest one or two points for consideration.

Examining the evidence brought forward:

1. I submit that it is not reasonable to assume that because conjunctivitis is prevalent within the first week of birth, therefore the maternal passages are “practically never sterile.” We have still to learn what numbers of the cases of conjunctival inflammation are due to simple, non-infected irritation by the vaginal secretions (? lactic acid), what numbers become infected immediately after birth (there is ample opportunity), and what numbers are infected in the vagina.

2. It is beyond dispute, of course, that every time sexual intercourse takes place the vagina is contaminated by a variety of organisms, but evidence of sepsis of the vagina at term which consists of proof (if proof were needed) that the organisms were introduced into the vagina by intercourse sometime during the pregnancy is not, I think, worth very much. Even if intercourse far on into pregnancy is the rule, there must be a period of one or two months during which there is no fresh infection, and there are at least two factors to be considered—in a question of evidence—during this period: the destruction or neutralisation of the organisms by the mother, and the possibility that the organisms may die or destroy each other from other causes.

3. I cannot understand Dr. Brock's “*very conclusive proof*” (my italics) of the capability of the uncleaned, but otherwise healthy, penis of causing puerperal sepsis. I should expect a rise of temperature after intercourse on the seventh night of the puerperium if the penis had been *boiled*.

But let it be granted that the passages at term are practically never sterile; what is the true significance of the organisms present? If a man presents his wife during her pregnancy with virulent germs from a diseased nethra it is one thing, but puerperal fever occurs in women whose genitals, and whose husbands' genitals, are healthy. Is there any evidence to show that in such a case the infection is due to organisms present in the vagina before labour?

On general grounds one would not expect intercourse during pregnancy by healthy people to be dangerous. It is not probable that a man and woman can both harbour in the genital region a germ of great virulence for months without symptoms. It must happen frequently that bacteria are placed during intercourse very near the cervical canal immediately before the onset of the menstrual flow and very soon after the period, almost certainly whilst there are raw areas in the uterus. It is reasonable to suppose that organisms (as well as spermatozoa) enter the uterus, and yet

no harm follows. I suggest that there is some factor (other than fatigue, size of wound, access to open vessels, &c., which, to my mind, do not meet the case) which operates to make a woman particularly susceptible during a particular labour.

Dr. Brock asks what a surgeon would say if he were asked to operate in a region so soiled as the vagina. Probably—"It might have been piles."—I am, Sir, yours faithfully,

Lansdowne-road, S.E., August 19th. R. L. KITCHING, M.B., B.S.

## Obituary.

WILLIAM SMITH GREENFIELD, M.D. LOND.,  
F.R.C.P. LOND. & EDIN.,

EMERITUS PROFESSOR OF PATHOLOGY AND OF CLINICAL MEDICINE IN  
THE UNIVERSITY OF EDINBURGH.

William Smith Greenfield was born at Salisbury and received his medical education at University College Hospital, London, graduating M.D. in 1874. In the same year he became demonstrator in morbid anatomy and pathology at St. Thomas's Hospital, where for two years previously he had been registrar. Later he became assistant physician and physician for diseases of the throat at the hospital. In 1878 he succeeded Dr. Burdon Sanderson as professor of pathology at the Brown Institute.

It was at St. Thomas's Hospital that William Greenfield laid the foundation of a great career in pathology, influenced by such leaders of thought as Wilson Fox and Murchison. When in 1881, he came to Edinburgh, he had already made his name as a teacher, a clinician, and a pathologist. Both at St. Thomas's and at the Brown Institute he made full use of all the material at his disposal and devoted himself with great enthusiasm to the study of contagious and infectious disease. His work on anthrax stands out as the record of a great scientific observer, and his original publication on "wool-sorter's disease" is still the classic on the subject. Encouraged and abundantly supplied with means by the French Government, Pasteur carried out a great piece of experimental work, which in 1881 resulted in a communication to the International Medical Congress in London dealing with a successful means of protecting animals against infection with *B. anthracis*. This work is justly recognised as one of the greatest contributions on the subject of vaccination, but it is not generally recognised that priority for the discovery must be given to Greenfield. Working with a small and inadequate sum of money furnished by the generosity of a private society, and hampered by the difficulties interposed by the law dealing with experiments on animals, he obtained the same results working with similar methods. His work was published in the Proceedings of the Royal Society in 1880.

Greenfield's work on the "Pathology of the Kidney," published by the New Sydenham Society, is, one of the most accurate pieces of pathological work on the kidney in the English language. All his other work shows the same accuracy and attention to detail. All pathologists regret that during his later years he did not give to the world of science the results of his wide experience, which would have been invaluable to all working in the same field as himself. Those of us who admire him most are fully conscious of this defect, which was largely due to self-consciousness. He was a critic of all scientific work, but his most severe criticism was reserved for his own and, though much work was got ready for publication, it never satisfied the demands of its author. This hypercriticism may be regarded as a great fault in a teacher, but though he did not publish widely, he gave his rich experience to those who worked under him, and the pathological world has benefited indirectly through the work of Woodhead, Muir, and the other professors of pathology and bacteriology who commenced their careers as Greenfield's assistants. Trained as a clinician and having the only sound basis for clinical medicine, a thorough knowledge of morbid anatomy and histology and experimental pathology, it is not surprising that in his introductory lecture at Edinburgh Greenfield said: "It is living matter with which we have to deal, and it is by the exact study of the phenomena of life that we must bridge over the chasm between dead morbid anatomy and living pathology." Or again: "The study of clinical medicine and pathological experiment are, in my opinion, the inseparable adjuncts of pathological study. That would be a strange physiology which should conduct its study on

dead animals alone, and no less strange a pathology studied only on dead subjects." Believing this, and striving with all his energy to give the living pathology to his students, one cannot wonder at his success—a success which is not measured, but which is partly shown by the number of his pupils who have held or are holding important posts in pathology and bacteriology in this country and in our Dominions. It may be said that the Pathological School of Edinburgh has in the past directed the pathological teaching of this country, and that largely because Greenfield inspired those who worked under him to search for truth. Never bound by old shibboleths but always sceptical of the new, he taught others to do that which he himself always did—viz., examine all new facts and theories brought forward, try them, and, if the evidence justified them, then have no hesitation in accepting them and making them bases for further work.

One of his best-known lieutenants thus writes about him: "To his assistants he was always ready to give help and advice, and I often marvelled at his knowledge of the literature of his subject. To be an assistant with him was both an honour and a privilege, for it was only those who were intimately associated with him who knew the real man. Sir German Sims Woodhead, in a letter to me the other day, said, 'I always look back to the period of association with Greenfield as a very pleasant and profitable time. I was fond of the man.' That, I am sure, will be the feeling of everyone who has been an assistant with him. We were drawn to him, not by the mere admiration of a student for a great and brilliant chief, nor by the pride of being associated with a really great pathologist, but by a real bond of friendship and love for the man. A severe but just critic, a man who could not tolerate slackness, and one who loathed toadyism in all its forms, it is not to be wondered at that he made enemies. But his enemies were never those who really knew him. To see him in his own home, to know his real interest in his students, and to have evidence, as I abundantly had, of the true greatness of his character, is to make me look back with pleasure to the years I spent with him. He himself has passed, but his memory must always remain to those, who, like myself, have been closely associated with him and who owe so much to him." J. M. B.

### LOVELL DRAGE, M.D. OXON.

THE profession has lost a valuable and well-known practitioner by the death, from septic poisoning, of Dr. Lovell Drage, of Hatfield. Born in 1859, he was educated at Winchester, Christ Church, Oxford, Owens College, Manchester, and at St. Bartholomew's Hospital, where he was house surgeon to the late Sir Thomas Smith, and resident midwifery assistant under Dr. J. Matthews Duncan. He took a science degree at Oxford in 1881, and proceeded to M.B., B.Ch. in 1887, and M.D. in 1893. After a distinguished career as a student and member of the junior staff at St. Bartholomew's, he joined his father in practice at Hatfield, Herts, and was for many years well known in the country and in medical circles in London. His tall figure and cheery greetings of numerous old friends were a feature of many meetings, whether social or scientific, in the medical world. In spite of the claims of large and important practice and much public work of an urgent character, Drage found time to pursue original clinical observation. His inquiry into the use of the derivatives of cinnamic acid in malignant disease is a case in point. Various papers on this subject from his pen appeared in the columns of THE LANCET, and though his views got no strong outside support, they obtained the respect earned by his obvious sincerity. A man of clear and decided opinions, he was a generous and straightforward opponent of those with whom he disagreed; but he will be remembered far more widely as a warm-hearted and genial friend.

Drage was a typical country sportsman, and in his earlier years a fine horseman and good shot. He had a faculty for preserving old friendships, many of them begun at school or at St. Bartholomew's Hospital, and a large group of men will regret the genuine and warm hospitality of the old house at Hatfield. He will be widely and acutely missed in his county of Hertfordshire, where among other important public posts he held the office of coroner, and in that capacity conducted the inquest upon the bodies of the crew of the Schutte-Lanz airship which was brought down in flames at Cuffley on Sept. 3rd, 1916. The sympathy of many will go out to his widow, his son, Major R. L. Drage, and his daughter.

## Parliamentary Intelligence.

### HOUSE OF LORDS.

WEDNESDAY, AUGUST 13TH.

#### *Closing of Dublin Hospitals.*

LORD SHANDON asked whether the attention of H.M. Government had been directed to the impending closing of the Houses of Industry Hospitals in Dublin; if it was intended to take any action relating thereto; and moved for papers. He said that he desired, if possible, to draw from the Government some sympathetic view and practical assistance in connexion with the serious difficulty that had arisen with regard to the management of four hospitals, which were essentially State hospitals, and at the present time were supposed to be supported by a grant from Imperial resources. This was really a serious matter which ought to be dealt with, and he hoped to suggest one practical way of dealing with it. In the eighteenth century there were established by the Irish Government of the time a series of hospitals to provide surgical and medical aid for the poorer classes in Dublin and Ireland generally, and these hospitals for a time fulfilled the functions now fulfilled by Poor-law relief hospitals. Under the Act of Union this was one of the liabilities taken over by the Imperial Government, and a short time after the operation of the Act of Union it was found that difficulties, both from a monetary and a practical point of view, arose with regard to these hospitals. Two inquiries were held. One was an inquiry by the House of Commons in 1854 and the second was an inquiry held by a commission, generally referred to as the South Commission, in 1856. The South Commission reported that these hospitals were doing such good work that they should be maintained in their then state of efficiency. The report of the South Commission was followed by an Act of Parliament called the Hospitals Regulation Act, 1856, which constituted the hospitals in their present form. They consisted of a group and were called the Richmond, a surgical hospital; the Whitworth, a medical hospital; the Hardwicke, a purely fever hospital; and the Auxiliary block for surgical and certain emergency services. These four hospitals were constituted under the statute with a government of a very peculiar character. The Lord-Lieutenant of Ireland, through the Irish Office, exercised complete control over the management of these hospitals. The buildings themselves were not private property, but were vested in the Commissioners of Public Works in Ireland, and nothing could be done in that way to mortgage or charge these buildings except with the Commissioners' approval. This showed how completely they were State institutions. But more than that, resulting from the recommendations of the South Commission, a sum of £7600 originally, and now £7500, per annum was provided as being sufficient to keep up these hospitals. From 1856, down to the beginning of the war, this grant was found sufficient—a rather tight fit, perhaps, but still sufficient—to keep them going. It was quite impossible to keep any institution going on the same rate of contribution that was possible before the war. He was informed that while prior to the war £64 12s. 11d. per patient was sufficient to keep the hospitals going, in 1919 the sum required per patient was £119 1s. 10d. In Dublin there were a number of hospitals supported by voluntary contributions, most of them being at present in debt. The difficulty of getting the public under present conditions to clear off debt or to keep the hospitals going in their old condition of efficiency was practically insuperable. These particular hospitals had no private subscriptions, and though the statute under which they were constituted did contemplate private subscriptions, the power had never been used, and the hope of getting money in present circumstances from private sources was, he was afraid, an impossibility. The four hospitals together were practically the largest institution of the kind in Ireland. The closing of them would not only affect the indigent poor, but seriously affect medical science and practice in Ireland. It would also seriously affect the training of nurses. The hospitals were practically closed and there was no chance of their being opened unless some practical solution was found. Perhaps a business inquiry representing the Treasury, the medical profession, the governors, and perhaps some of the business men of Dublin, might come to some conclusion. The doctors said, he was informed, that suddenly to shut down one of these hospitals was practically impossible. If they shut down the fever hospital there would be no sufficient accommodation for fever patients in Dublin. If the emergency block were shut down they would have to take serious cases across the city in cars or ambulances, with great suffering to the patients. The doctors said it was practically impossible. Surely some solution might be found before the winter.

The Earl of MAYO supported Lord SHANDON's motion, and expressed the view that he had made out a strong case for these hospitals, which were much needed in Dublin.

The Earl of CRAWFORD (Chancellor of the Duchy of Lancaster), replying for the Government, said these hospitals were not State hospitals in the sense that they rendered any special service to the State. They differed in no degree from any other hospital in Ireland or in Great Britain, except that they had the good fortune for many years to have received a special grant. From accounts he had before him it would certainly appear that the State subsidy of £7600 was not the only source of income available to this charitable institution.

LORD SHANDON: It is the only one except the private patients.

The Earl of CRAWFORD, continuing, said that during the last two or three years the hospital had had a very considerable income from the War Office apart from the money voted by Parliament. Last year it was £7000; the year before £6300; this was in addition to the income from patients who could afford to pay.

LORD SHANDON: They are not very large, but there are some.

The Earl of CRAWFORD: They are upwards of £3000 a year. He was afraid he could not hold out hopes to the noble and learned Lord that the Treasury would see its way to recommend Parliament to pay a larger sum than the present annual grant. He did not think it would be wise to do so.—The motion was by leave withdrawn.

#### *War Pensions Bill.*

Their Lordships went into Committee on the War Pensions (Administrative Provisions) Bill, the Earl of Kintore in the chair. On Clause 8 (dealing with appeals to Pensions Appeal Tribunals),

The Earl of CRAWFORD moved an amendment to provide that no appeal should lie in the case of any claim already heard and rejected by a Ministry Appeal Tribunal. This prevented a man having his case dealt with by a new tribunal after it had already been settled by a competent tribunal in existence.

The amendment was agreed to.

The Committee stage of the Bill was concluded, the Bill was reported and read a third time and passed.

### HOUSE OF COMMONS.

WEDNESDAY, AUGUST 13TH.

#### *Medical Breakdown in Afghan Campaign.*

Major EARL WINTERTON asked the Secretary of State for India if he would state what steps he was taking to inquire into the allegations regarding transport and medical breakdown in the Indian Army operations against Afghanistan.—MR. MONTAGU replied: I have caused inquiry to be made on every definite allegation that is brought to my notice and I hope to lay papers on the table very shortly dealing with the medical arrangements in the North-West Frontier campaign.

Lieutenant-Colonel SIR S. HOARE: Will the papers be laid before the rising of the House for the holidays?—MR. MONTAGU replied: I do not yet know when the House is going to rise, but I want to get out the telegrams that I have received from the Government of India as soon as possible and I hope to have the papers ready at the end of this week.

#### *Small-pox in the Country.*

MR. CLOUGH asked the Minister of Health if he would state how many cases of small-pox there were in this country, and whether any of them had been introduced from outside.—Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: During the month of July and the first week in August 60 cases of small-pox have come to the knowledge of the Ministry of Health. Of these one group of cases numbering 25 up to August 7th is associated with the return home of a sailor and three groups numbering eight cases in all up to August 7th to soldiers returning home from abroad. There have been three ship-borne cases intercepted by port sanitary authorities from which there has been no spread of infection.

#### *A Pensions Disablement Appeal.*

SIR MONTAGUE BARLOW asked the Pensions Minister whether he would have inquiries made into the case of Mr. A. Wakefield, late able-bodied seaman No. 16,273, of H.M.S. *Ruby*, of 15, Enbridge-street, Trafford-road, Salford; whether this man was invalided from the Navy with flat feet caused through wounds in the leg and ankle after 17 years' service, having joined at the age of 15½ years; whether, on discharge, he was awarded a temporary pension; whether he applied to the local War Pensions Committee for reassessment and was examined by the medical referees on April 29th; and whether, in spite of the fact that his recommendations were forwarded to the Ministry of Pensions and a further medical board ordered, the man was still unable to ascertain what pension, if any, has been awarded to him.—SIR J. CRAIG replied: Mr. Wakefield was invalided for injury to his right leg and was in receipt of disablement pension until May 15th, 1919. The disability of flat feet has been found to be neither attributable to nor aggravated by service. He was medically examined on March 6th, 1919, when the disablement arising from the

injury was assessed at nil. He therefore reverted to a pension of 4s. 8d. a week for life awarded in respect of his service. On an appeal being received from the local War Pensions Committee on his behalf he was further examined on June 3rd, 1919, when the extent of disablement was again assessed at nil. He is therefore ineligible for resumption of his disablement pension, and the fact has now been communicated to him.

THURSDAY, AUGUST 14TH.

*The Isolation of Tuberculous Patients.*

Mr. GRATTAN DOYLE asked the Minister of Health if he was aware that at the Northern Hospital, Winchmore Hill, London, certain wards were used for consumptive patients in all stages of the disease, the patients including men, women, and children, while other wards were being used for children convalescent from scarlet fever and diphtheria removed from other infectious hospitals; if his attention had been drawn to the fact that the whole of the wards referred to were enclosed in one building, that the nursing staff was presided over by one matron, and that the nurses were employed indiscriminately in either infectious or tuberculosis wards; whether, if he decided that the hospital should still house both classes of patients, steps would be taken to appoint a recognised expert to take responsible charge of the tuberculosis wards; and if he would ascertain if there was sufficient and suitable space for recreation for sanatorium patients.—Major ASTOR replied: Some blocks at the Metropolitan Asylums Board Hospital, Winchmore Hill, are used for the treatment of tuberculous patients and other blocks for convalescent cases of acute infectious disease, but no ward and no block is used for more than one disease. The tuberculous patients are classified in their respective wards according to the stages of the disease. A nurse engaged in nursing tuberculosis is not allowed to come into contact with cases of acute infectious disease. An entirely separate medical staff, with special experience in tuberculosis, under the general supervision of the medical superintendent of the hospital, is in charge of the blocks for the treatment of tuberculosis. Having regard to the class of cases admitted to these blocks the space available for recreation is sufficient and suitable.

*Grants to Panel Practitioners.*

Mr. GODFREY LOCKER-LAMPSON asked the Minister of Health if he would state what was the cost each year of the grants made and promised to panel doctors and chemists in respect of war bonuses or allowances.—Major ASTOR replied: Grants by way of war bonuses or allowances as distinct from the regular payments for remuneration for insurance practice have been made to insurance practitioners in respect of the year 1918, amounting to approximately £300,000. Approval has been given by the Treasury for the grant of a war bonus to insurance practitioners in respect of the year 1919 on a basis corresponding broadly to that laid down by the Conciliation and Arbitration Board for Civil Servants. The cost of the grants for the year 1919 is estimated to be approximately £950,000. These figures are for Great Britain. As regards chemists, the increase in remuneration afforded them in respect of war conditions forms part of a general charge upon funds provided for defraying the cost of medical benefit, and cannot be readily separated.

*Medical Officers obtained by the War Office.*

Major FARQUHARSON asked the Secretary for War if he would state the number of new medical officers which had been obtained by the War Office upon the consolidated rates of pay offered at the commencement of July of this year.—Mr. FORSTER (Financial Secretary to the War Office) replied: The number of new medical officers obtained is 27.

*Release of Medical Officers in the Army.*

Major FARQUHARSON asked the Secretary for War (1) if he was aware that the contract under which a number of medical practitioners held temporary commissions in the Royal Army Medical Corps would expire on the date on which the termination of the war was officially declared; and what arrangements had been made to enable those practitioners now serving in India and Mesopotamia to return to this country immediately on the termination of their contracts; (2) if he would state under what authority medical and other officers were being temporarily retained in India; and what steps were being taken to ensure the immediate release of those medical officers who were marked for early demobilisation by the Ministry of National Service prior to April of this year.

Mr. BENNETT asked the Secretary for War whether, in view of the fact that Royal Army Medical Corps officers in India serving under yearly contracts were to be demobilised previously to those who volunteered for the duration of the war, he would consider the claim to compensation of officers of the latter category whose practices, which they had built up by their exertions and for which they paid substantial sums, had been virtually ruined and absorbed by the large number of medical officers demobilised from France and other theatres of war; and whether he would

state how many temporary medical officers, exclusive of sick, had been sent home from India since the armistice and how many remained in India.—Mr. FORSTER replied: Temporary medical officers are being retained in India under the terms of their contracts, which render them liable for service for the duration of the present emergency. The only officers who are serving on yearly contracts are those who are not liable to the Military Service Act, and cannot therefore be retained beyond the termination of their contracts. The contracts of temporary officers serving for the duration of the present emergency terminate on the statutory date for the end of the war, and everything possible will be done to enable them to be returned to the United Kingdom by that date. In the event of this being effected the question of compensation does not arise. One hundred and forty-five temporary, Special Reserve, and Territorial Force officers (exclusive of sick) have been sent home since the armistice, and 335 remain, including 100 officers temporarily detained while en route from Mesopotamia on account of the situation prevailing in India. I would add that every available medical officer who is liable for further service is being placed under orders for India or Egypt in order to relieve those who have been asked for by the Ministry of National Service.

MONDAY, AUGUST 18TH.

*Neurasthenia and Shell Shock Treatment in Ireland.*

Lieutenant-Colonel WALTER GUINNESS asked the Pensions Minister whether he was now in a position to make a statement on the provision for the accommodation and general treatment of disabled men in the southern region of Ireland who had been discharged suffering from neurasthenia and shell shock; whether accommodation could be found for such invalided men who were on the borderline of lunacy, and who in consequence must be detained, even against their wishes, in institutions; whether he was aware that the authorities of the two institutions in the neighbourhood of Dublin were prohibited from detaining men against their wishes and, therefore, that such institutions were of little value in the case of neurasthenia or shell shock that bordered on lunacy; whether he was aware that in the absence of such accommodation most of the men in question who had no homes were living in lodging-houses, that a few were certified as being potentially dangerous, that the procedure of getting men into an asylum was troublesome and lengthy, and that on more than one occasion before the admission of the man to an asylum had been secured friends interested in his welfare had lost sight of him; whether he considered it satisfactory that ex-Service men should be committed to lunatic asylums in Ireland and treated as paupers in accordance with the Lunacy Laws as they operated in Ireland; whether provision could be made at once to set up a separate institution for the Southern region of Ireland, to which such cases might be admitted and detained for a time even against the wishes of the patient; and whether the scientific treatment accorded to such cases at the Seale Hayne Institution could be introduced into Ireland.—Sir L. WORTHINGTON EVANS replied: I have no power to keep any man in an institution against his will unless he is certified under the Lunacy Laws. A man so certified and sent to an asylum in Ireland has hitherto been treated as an ordinary patient, but under a scheme which will come into force at an early date he will in future be treated as a Service patient. Arrangements are being made to establish a neurological hospital in the South of Ireland for ex-Service men at which scientific treatment for neurasthenia and shell shock will be provided.

*Seale Hayne Hospital.*

Mr. LAMBERT asked the Secretary for War if he could now state definitely when the Seale Hayne Military Hospital, Newton Abbot, would be evacuated.—Mr. CHURCHILL replied: The work of reinstatement is proceeding as rapidly as is possible, but I am afraid that it is not yet possible to fix a definite date. Three out of the four blocks of the building are empty and are ready for handing over to the owners, who, however, are not prepared to take over portions of the hospital and prefer to wait until the whole can be handed over on the completion of reinstatement. At the present moment the laboratory is being reinstated, and the reinstatement of technical and scientific apparatus is a matter which necessarily takes some time.

*Clothes of Asylum Patients.*

Sir J. BRUTON asked the Home Secretary whether he was aware that Service or ex-Service men when sent to lunatic asylums were put into pauper clothes until the asylum authorities were notified by the Home Office; that they accepted them as Service patients; and, pending acceptance (which might not be given for six weeks to three months), whether it would be possible to allow these men to wear their Service or civilian clothes, and thus avoid the distress caused to their relatives on finding them in pauper attire.—Mr. SHORTT replied: Ex-Service men sent to lunatic asylums direct from war hospitals under Section 91 of the Army Act or Section 3 of the Naval Enlistment Act, 1884, are immediately transferred to the

private class, and as private patients are allowed to wear their own clothes. This class form the hulk of the ex-Service men admitted to asylums. Ex-Service men admitted on summary reception orders after discharge from the Army or Navy are chargeable to the rates until their eligibility to be classed as "Service" patients has been investigated by the Ministry of Pensions, and they are clothed for the time being as ordinary patients. Where a medical superintendent has reason to believe that a man of the latter class will be accepted as a "Service" patient I think he might properly allow such a patient to wear his own clothing, and I will ask the Board of Control to make this suggestion to the asylum authorities.

#### *Tuberculous Ex-Service Men.*

Lieutenant-Colonel Raw asked the Minister of Health if he would state what steps he proposed to take in connexion with the recent report of the inter-departmental committee on tuberculous ex-Service men in view of the urgency of the matter.—Mr. TOWN JONES replied: The report has been in my right honourable friend's hands for a very short time; and while he quite agrees that the matter is urgent, he is not yet in a position to state what action the Government propose to take.

#### *Medical Inspection of Aliens.*

Mr. C. K. MURCHISON asked the Minister of Health if a decision had been reached, in conjunction with the Home Office, concerning the regulations to be carried out in the medical inspection of aliens arriving in this country; and, if so, whether these regulations could now be published.—Mr. TOWN JONES replied: An Order in Council containing further provisions with regard to the medical inspection of aliens will be issued at an early date. I will see that a copy is sent to my honourable friend when available.

#### *Expenses of Port Sanitary Authorities.*

Mr. MURCHISON asked the Minister of Health whether he would consider the desirability of taking steps to secure that the cost incurred by the port sanitary authorities, especially in East Coast ports like Hull and Newcastle, in protecting the people of this country from the inroads of infectious diseases from abroad should be treated as a national charge at least to the extent of 50 per cent. of the amount so incurred.—Mr. TOWN JONES replied: Yes, sir, this question is already under consideration.

#### *Scottish Board of Health.*

Mr. JOSEPH JOHNSTONE asked the Secretary for Scotland whether he was aware that the Minister of Health for England was now in process of forming the consultative councils provided for under the Ministry of Health Act; and whether he proposed similarly to appoint the consultative council provided for under the Scottish Board of Health Act.—Mr. PRATT (Parliamentary Secretary to the Scottish Board of Health) replied: The answer to the first part of the question is in the affirmative. The proposals of the Scottish Board of Health for the establishment of consultative councils are being embodied in a draft Order in Council. The actual constitution of the councils must, however, await the fulfilment of the requirements of the Act as to the Order in Council lying before Parliament for 30 days.

TUESDAY, AUGUST 19TH.

#### *V.A.D. Nurses and Gratuities.*

Mr. HOGGE asked the Financial Secretary to the War Office whether Voluntary Aid Detachment nursing members who had worked in military hospitals received gratuity; whether Voluntary Aid Detachment general service members working in the same hospitals received no gratuity; whether, if a Voluntary Aid Detachment nurse had served any part of her time as a general service member, she was debarred from gratuity; and whether he could revise these anomalies.—Mr. FORSTER replied: The facts are as stated, except that a nurse is not debarred from gratuity on her service in a non-professional capacity. The nursing members receive gratuity because they are part of the nursing service; the general service members receive, instead, furlough and out-of-work donation on termination on the same lines as members of the Queen Mary's Army Auxiliary Corps. It is not proposed to make any change.

#### *Patients in Military Hospitals.*

Major GLYN asked the Secretary for War if any arrangement had been arrived at with the Ministry of Pensions in regard to patients under treatment in military hospitals that were to be taken over by the Ministry of Pensions; and whether the arrangements insured the continuance of treatment by the doctors and nurses who had had previous charge of all non-convalescent cases.—Mr. FORSTER replied: An arrangement has been arrived at. The staff will not be transferred en bloc, as transfer is dependent in part on the wishes of the individuals, but no doubt the Ministry of Pensions will be glad to take into their service as many as possible of the old staffs who are desirous of remaining.

## Appointments.

WORSTER-DROUGHT, C., M.B., B.C. Cantab., has been appointed Honorary Neurologist to Out-patients, Bethlem Royal Hospital.  
St. Thomas's Hospital: WAYTE, J. W., M.R.C.S., L.R.C.P. Lond., M.B., B.Ch. Cantab., BROWN, E. P., M.R.C.S., L.R.C.P. Lond., M.B., B.Ch. Cantab., BROCKMAN, E. P., M.R.C.S., L.R.C.P. Lond., CARTER, E. E., M.R.C.S., L.R.C.P. Lond., MOOR, F., M.R.C.S., L.R.C.P. Lond., PROCTOR, R. A., W. M., M.C.S., L.R.C.P. Lond., Casualty Officers and Resident Anesthetists: SMITH, J. F., M.R.C.S., L.R.C.P. Lond., AMOS, S. K., ECCLES, C. Y., M.R.C.S., L.R.C.P. Lond., THOMAS, A. E., M.B., B.Ch. Oxon., Resident House Physicians: LE GROS CLARK, W. E., M.R.C.S., L.R.C.P. Lond., SPROTT, N. A., M.B., B.Ch. Oxon., WALKER, J. P., S. M.B., B.Ch. Oxon., HIGGINS, L. G., M.B., B.Ch. Cantab., Resident House Surgeons: RYAN, J. F., M.R.C.S., L.R.C.P. Lond., House Surgeon: POTTER, A. F., M.R.C.S., L.R.C.P. Lond., BIAGER, W. G., D.S.O., M.B., B.Ch. Cantab., Obstetric House Physicians: DICKSON, D. McV., M.R.C.S., L.R.C.P. Lond., EVANS, H. L., M.R.C.S., L.R.C.P. Lond., Ophthalmic House Surgeons: SMITH, F. P., M.R.C.S., L.R.C.P. Lond., Clinical Assistant to the Throat Department: VINCEY, A., M.R.C.S., L.R.C.P. Lond., Clinical Assistant to the Children's Medical Department.  
Certifying Surgeons under the Factory and Workshop Acts: WILSON, J. C., M.B., B.Ch. Belf. (Ballyward); STEWART, J. K., M.B., Ch.B. Belf. (Randallstown); AITKEN QUINE, W. J., M.B., B.S. Lond. (Chapel-en-le-Frith); SELKIRK, A., M.B., C.M. Edin. (Cowdenbeath); DOBHOE, D. B., L. & L.M.R.C.P. & R.C.S. Irel. (Rathvilly).

## Vacancies.

Dumfries and Galloway Royal Infirmary.—Res. Asst. H.S. £75.  
East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.S. £125.  
Evelina Hospital for Children, Southwark, S.E.—H.S. and H.P. £160.  
Finchley Urban District.—M.O.H. and Sch. M.O. £600.  
Garmang County Asylum, Bridgend.—Fourth Asst. M.O. £400.  
Glasgow, Royal Samaritan Hospital for Women.—Asst. Visiting S.'s.  
Great Yarmouth Hospital.—H.S. £200.  
Greenwich Union Infirmary, Vanbrugh Hill, East Greenwich, S.E.—Deputy Med. Supt. £400.  
Guisborough Union.—M.O. £700.  
Hong-Kong University.—Lecturer in Biologv. £400.  
Isleworth Infirmary.—Sec. Asst. to Med. Supt. £300.  
Italian Hospital.—H.S. £150.  
Khartoum, Wellcome Tropical Research Laboratories.—Asst. Bacteriologist. £2,600.  
King's Lynn, West Norfolk Hospital.—H.S. £150.  
Leeds Public Dispensary, North-street.—Res. M.O. £200.  
Leeds Searcroft Hospitals for Infectious Diseases.—Res. M.O. £300.  
Leyton U.D.C. Education Committee.—Asst. M.O. £350.  
Liverpool, David Lewis Northern Hospital.—Three S.'s and Two P.'s. £150.  
Liverpool Royal Infirmary.—Hon. Asst. Gynaecol. S.  
Liverpool School of Tropical Medicine.—Tropical Research, Brazil. £350.  
London County Council.—Fourth and Fifth Asst. M.O.'s at London County Mental Hospitals. Fourth Assts., £425 to £500; Fifth Assts., £300 to £400.  
Maidstone, Kent County Ophthalmic Hospital.—Hon. Oph. S.  
Manchester, Ancients Hospital.—Res. S.O. £200.  
Manchester Children's Hospital.—Asst. S. £50.  
Manchester, Mousall Fever Hospital.—First Med. Asst. £350. Second Med. Asst. £300.  
Manchester Royal Infirmary.—Med and Surg. Registrars. £75.  
Surg. Tutor. £30. Also H.S.'s. £25.  
Melbourne University.—Lecturer in Pathology. £600.  
Middlesbrough, North Yorkshire Hos. Ital.—Asst. H.S. £175.  
Middlesex County Council.—Female Asst. M.O. £500.  
National Hospital for Diseases of the Ear, Westmoreland-street, W.—Res and Non-Res. M.O.'s. £100 and £50.  
Nelson, Lancs.—M.O. II. and Sch. M.O. £700.  
Newport Borough Asylum, Caelecon, Mon.—Asst. M.O. £350.  
Northampton General Hospital.—Pathologist. £750.  
Northamptonshire C.C. Education Committee.—Sch. Dentist. £350.  
Oldham County Borough.—Asst. M.O.H. £450.  
Preston Royal Infirmary.—Res. H.S.  
Prince of Wales's General Hospital, Tottenham.—Hon. Asst. P. and Hon. Asst. Ophth. S. Also Clin. Asst.'s.  
Putney Hospital, S.W.—Res. M.O. £50.  
Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—H.S. and Cas. H.S. £100 each.

Rochdale Infirmary and Dispensary.—Sen. H.S. £200. Also Jun. H.S. £100.  
 Roll of Honour Hospital for Children, 688, Harrow-road, W. 10.—  
 Ohio, Assts.  
 Rotherham Hospital.—Senior H.S. £250.  
 St. Helens Education Committee.—Whole-time Dentist. £450.  
 Sheffield City Education Committee.—Sch. Dental S's. £350.  
 Sheffield Royal Infirmary.—H.S. for Ear, Nose, and Throat. £150.  
 Shetland.—Fingwall, Whiteness, and Weisdale.—M.O. and Pub. Vac. £45.  
 South Africa, Mental Hospital Service.—Asst. P.'s. £380.  
 South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Junior H.S. £175.  
 Southampton, Free Eye Hospital.—H.S. £150 to £200.  
 Swansea General and Eye Hospital.—Res. M.O. £250.  
 Taunton and Somerset Hospital.—Res. Asst. H.S.  
 Warwickshire County Council.—Female Asst. M.O.H. £400.  
 Westminster Hospital, Broad Sanctuary, S.W.—H.P.  
 Winsley Sanatorium, near Bath.—Asst. Res. M.O. £250.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Wadebridge, Port Glasgow, Paisley, and Dundrum.

## Births, Marriages, and Deaths.

### BIRTHS.

GARDNER.—On August 15th, at Merlon-street, Oxford, the wife of A. Duncan Gardner, M.D., F.R.C.S., of a son.  
 KEYNES.—On August 14th, at Grove House, Hollywood-road, S.W., the wife of Geoffrey Keynes, M.D., of a son.  
 TATHAM.—On August 10th, at Ealing, the wife of Captain G. T. P. Tatham, R.A.M.C., of a daughter.  
 WELLS.—On August 17th, at Birchwood, Fleet, Hants, the wife of Major A. G. Wells, D.S.O., R.A.M.C., of a son.

### MARRIAGES.

HEBERT—TATTON.—On August 12th, at St. Andrew's Church, Holborn, Godfrey Taunton Hebert, M.D., to Constance, youngest daughter of the Rev. D. and Mrs. Tatton, of Moorlands, Edgware.

### DEATHS.

DRAGE.—On August 14th, at North Place, Hatfield, Lovell Drage, M.D. GREENFIELD.—On August 12th, at Muir House, Juniper Green, William Smith Greenfield, M.D., LL.D., Emeritus Professor of Pathology in the University of Edinburgh.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.  
 LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton:—

MONDAY, August 25th.—4.30 P.M., Lecture VII.—Gastric Ulcer. Complications, Treatment.

FRIDAY.—4.30 P.M., Lecture VIII.—Surgical Anatomy of the Duodenum and Paucereas. (In the Dissecting Room.)

A Course of Clinical Lectures for Advanced Students on Intermittent Blood Infections and their Relation to Certain Common Diseases of the Kidney, Prostate, Testicle, and other Organs will be delivered by Mr. F. Kidd:—

WEDNESDAY.—4.15 P.M., Lecture IV.—Etiology and Pathology of Intermittent Blood Infections and their Relation to General Medicine. Intermittent Blood Infection as a Common Factor in the Causation of Disease. The Importance of this Conception for the Future of Preventive Medicine.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. H. K. Abbott, Knowle; Dr. R. W. Allen, Lond.; Dr. F. L. Apperly, Lond.

B.—British Colloids, Ltd., Lond.; Dr. J. M. Beattie, Liverpool; Dr. E. A. Barton, Lond.; Dr. E. C. Bousfield, Lond.; Dr. S. G. Billington, Wolverhampton; Mr. H. Birrell, Ealing.

C.—Miss H. Chick, Lond.; Mrs. E. J. Coles, Eynsham; Dr. C. R. Corfield, Manchester; Caxton Press, Lond.

D.—Demobilised Médico; Decimal Association, Lond.; Major A. Drury, R.A.M.C.; Dr. R. R. Eager, Exminster; Surg.-Gen. Sir G. Evatt.

E.—Dr. F. E. Fremantle, Hatfield, Lond.; Capt. T. P. Greenwood, R.A.M.C.; Mr. P. Geddes, Lond.

F.—Capt. H. A. Haig, R.A.M.C.; Dr. R. C. Holt, Didsbury; Messrs. W. Heffer and Sons, Cambridge.

G.—Dr. D. W. C. Jones, Lond.; Mr. R. L. Kitching, Lond.; Mr. H. Lucas, Wigan; Dr.

C. E. Lakin, Lond.; Rt. Hon. Lord Mayor of Lond.

M.—Ministry of Health, Lond.; Dr. J. McIntosh, Lond.; Dr. I. Moore, Lond.; Mr. A. Miller, Dublin; Dr. A. Maude, Hatfield; Mr. D. M. Macleod, Evesham.

O.—Dr. S. Otobe, Lond. P.—Messrs. G. P. Putnam's Sons, Lond.

R.—Dr. J. D. Rolleston, Lond.; Royal Medical Benevolent Fund, Lond., Sec. of

S.—Dr. W. J. Shaw, Donington; Secretary of State for the Home Department, Lond.; Mr. B. Sutton, Lond.; St. Thomas's Hospital Medical School, Lond., Sec. of; Dr. J. A. Shaw-Mackenzie, Balblair.

T.—Dr. H. A. Thompson, Lond.; Dr. F. E. Tylecot, Manchester; Mrs. J. F. Todd, Lond.; Dr. A. T. Todd, O.B.E., Huddersfield.

V.—Dr. F. Vicars

W.—Mr. E. M. Wood, Lond.; Dr. G. Ward, Sevenoaks; Dr. L. A. Weatherly, Bournemouth; Capt. A. C. Wilson.

## Notes, Short Comments, and Answers to Correspondents.

### STAMMERING AND VOICE DEFECTS.

BY MABEL V. O. OSWALD,  
 SPEECH SPECIALIST; LATE 1ST SOUTHERN GENERAL HOSPITAL,  
 NEUROLOGICAL SECTION, BIRMINGHAM.

With a Preliminary Note by Dr. J. N. ROBINS.

Dr. J. N. ROBINS, lately in charge of the Neurological Section at the 1st Southern General Hospital, writes as follows:—

"The paper on Stammering and Voice Defects, written by Miss Oswald, will be appreciated by the members of the medical profession as it illustrates in a simple and comprehensive manner a line of treatment which was found to yield highly satisfactory results. Miss Oswald's assistance in the treatment of functional voice defects was of much value, alike to her patients and to me as officer in charge of the Monyhull Neurological Section of the 1st Southern General Hospital. There appear to be two schools of thought on the treatment of stammering: (1) deals with the psychic cause and leaves the symptoms (stammering, aphonia, &c.) alone; and (2) deals with the symptoms (stammering, &c.), and leaves the psychic cause alone. Both of these appear to me to be wrong, for in the first case Scylla is avoided but the danger of Charybdis remains, and in the second case the reverse happens. Therefore, let us take a middle path and deal by mental exploration with the underlying unrecognised cause, and also the symptom by re-education; in this way really good results may be achieved."

### Experimental Treatment.

Stammering and functional voice defects have until recently been looked upon as unfortunate disabilities, and no real scientific attempt was made thoroughly to deal with such cases, and hence there was no recognised cure. Various treatments have been in vogue, each one more or less experimental.

The more successful regarded stammering as the result of some purely physical cause—i.e., incorrect respiration, spasmodic contractions of the laryngeal muscles, incoordinated movements of the organs of articulation, &c. Hence the treatment was directed to the correction of these physical disabilities exclusively. In many cases the actual speech defect was overcome, but as a rule the treatment was a prolonged one and the cure by no means permanent, the speech defect (in varying degree) tending to reappear.

### Tricks Designed to Overcome Speech Defects.

In some cases the patient was taught to resort to tricks in order to overcome his difficulty—e.g., when commencing to speak: (1) to pitch his voice on a note higher or lower than his natural-speaking voice; (2) to resort to certain rhythmical gestures to induce smooth speech; (3) to "sing" his words; (4) to press his knee firmly with the right hand; (5) or even to hold a pebble in his mouth!

Such methods of treatment obviously could not cure, and have done much harm in making the general public distrustful as to the possibility of a genuine cure. That such means were attended by any fleeting success is probably due to the fact that the patient's attention for the time being was diverted from his speech anxiety to the very unusual method of cure, the later being far more inconvenient, as a rule, than the original disability.

### Stammering Dependent on a Psychic Cause.

The frequent occurrence of stammering, mutism, and aphonia during the war, in patients with no such pre-war history, has opened a field of inquiry which has had considerable attention paid to it by those medical officers who have been trained in psycho-therapy. It has now been established that stammering is dependent on a psychic cause, with which it is necessary to deal adequately. Hence the original cause of the speech defect is psychological, the stammer being the expression of a memory of some painful nature which is either wholly or partially repressed.

The presence of a stammer, however, gives rise to the feeling of "fear of speech," and the patient loses confidence in his ability to speak before others. He then tries to force himself to speak naturally, but this, as a rule, only results in incorrect respiration, spasmodic contraction of the laryngeal and other muscles, and incoordinated movements of the organs of speech. By degrees these uncontrolled movements, incorrect breathing, &c., become established, which in turn cause the speech defect to become more fixed. This, then, is a secondary and not the original cause of the speech defect.

communications relating to editorial business should be addressed exclusively to the Editor of THE LANCET, 423, Strand, London, W.C. 2.

From regarding stammering as a purely physical defect, to be remedied solely by treating the physical symptom, at the present time there may be a danger of going to the opposite extreme and looking upon it as a symptom which will automatically disappear when the underlying psychical cause has been discovered and fully explained to the patient.

In cases of mutism and aphonia, however, the symptom does tend to disappear automatically. The underlying psychic cause is discovered and brought into consciousness, and by means of strong suggestion the patient is induced to use his voice, which invariably he is able to do. At this juncture, in order to avoid any resultant stammer, care must be taken that the patient produces his voice correctly and has been convinced of his ability to continue speech. This is important, as so many cases of mutism and aphonia become stammerers—i.e., their voice returns, but "anxiety" as to their ability to continue producing it results in a stammer. Convince the patient, and the anxiety disappears and there is no resultant stammer.

#### *Cases Successfully Treated.*

One case of aphonia—the result of gassing and being buried by shell—had persisted for nine months in spite of various treatments (massage, electrical treatment, &c.) tried previously in other hospitals. I treated the patient on the lines indicated above, and he was cured in two treatments (of about half an hour each) with no resultant stammer.

In another case the patient lost his voice gradually and the aphonic condition had persisted for nine months. I treated him similarly and he was cured in two treatments with no resultant stammer.

Another case I treated had already lost his voice twice as a result of gassing; the first time (4/8/16), he recovered his voice after three weeks in hospital; the second time (18/9/18) he was gassed again and aphonia had persisted for two months, when he was sent to me. He also was cured with no resultant stammer; and similarly other cases.

But in my experience with cases of stammering—especially those of long standing—the removal of the psychic cause does not necessarily mean that the symptom (stammering) disappears automatically. Logically, this should be so, since stammering (like tremors, monoplegias, &c.) is the outward expression of the patient's subconscious mental state. In practice, however, the stammer tends to remain even though the repressed memories have been brought to the surface and rendered ineffective. This is probably explained by the fact that an incorrect habit of breathing and speech production has been acquired, which the patient must voluntarily overcome.

#### *"Mental Exploration" and "Speech Relief."*

In the stammering cases I have treated the quickest results have been obtained where the patient has been treated both physically and psychically—i.e., by giving him certain respiratory and voice exercises together with strong suggestion, at the same time the psychic cause being removed by means of "mental exploration,"—and this latter can only be successfully accomplished by those with knowledge of psychological medicine. In order to effect a cure, therefore, it is obviously necessary to discover the original psychic cause of the stammer.

Hence the method of procedure would be, first, to explain fully to the patient why he stammers; next, and especially in cases of severe stammer, to give the patient "speech relief" by showing him how to breathe correctly, relax his muscles, &c., at the same time using strong suggestion that he will be able to read or say a certain thing correctly and not permitting him to fail. The patient having obtained an initial success must be convinced that he is able to repeat it, and so led to perceive that the cure in reality depends upon himself. By these means of re-education the patient will have gained confidence and lost to some extent "the fear of his own speech," but a permanent cure will not be effected till the psychic cause has been explored.

#### *Examples of Treatment.*

The following are a few practical examples of the above method of treatment. In each case the psychic cause was being specially dealt with by neurological medical officers:—

I had a patient with a very severe stammer dating from September, 1918, when he had been blown up by a shell and left dazed. He was being treated by one of the neurological medical officers who sent him to me for his stammer. I gave him certain breathing and voice exercises, which enabled him at once to speak with less difficulty. By means of strong suggestion he was able to read aloud without stammering. I explained things to him and convinced him that, having done so once, he could repeat it, and that the cure now depended on himself. He determined he could and would be successful. I saw him once again (making two treatments in all), when he was able to read aloud and speak with no difficulty and continued to do so.

Another patient had a nervous hesitating stammer when I saw him. He had been blown up and four months later had lost his voice. Aphonia had persisted for seven months, when his voice returned under treatment, leaving, however, this stammer. He was sent to me for treatment. In this case I chiefly used strong suggestion to convince him of his ability to speak with no stammer. He was cured in two treatments.

Another patient with a stammer of three months' duration—after aphonia of eight months—was convinced that he could not be cured.

He stammered badly while reading and speaking. I explained things to him and gave him certain breathing and voice exercises, showing him how to control his breath while reading. I then made him read aloud which, after a few attempts, he did with no stammer. When I saw him the second time, he said the stammer now only affected him if nervous. I again explained the nature of his stammer and by strong suggestion convinced him he could overcome it. After four treatments he could read and speak fluently on all occasions.

#### *Pre-War Stammerers.*

Similar treatment will be found to apply to pre-war stammerers. In these cases the habit of incorrect speech production is more strongly fixed and, therefore, will take rather longer to remove, but the permanency of the cure will depend (as in cases of war neuroses) on the removal of the psychic cause which originated the stammer.

One patient I treated, who had stammered very severely since experiencing a bad fright in early manhood (in civil life). He joined up and out of two years' foreign service had spent 11½ months off and on in hospital. While recounting the bad fright experienced years ago, the stammer became extremely severe, at times totally inhibiting speech, accompanied by tremors, &c. His respiration was incorrect, with spasms of the diaphragm. I explained to him why he stammered, and gave him special breathing and voice exercises, showing him how to relax his muscles. I then made him read aloud, which he did fairly. At subsequent interviews the stammer and tremors were much less marked, till the patient was able to talk over his experience with absolute calm and no attendant stammer. He had eight treatments altogether, after which he could speak and read aloud fluently on all occasions.

Another patient had stammered slightly since six years of age, the stammer increasing after experiencing air-raids. When I saw him the stammer was very severe, his breathing incorrect and uncontrolled, accompanied by strong muscular contraction of the laryngeal and other muscles during speech. I explained his stammer to him, showed him how to breathe diaphragmatically and to relax his muscles, and in ten treatments he was speaking and reading aloud with no stammer.

#### *Stammering in Young Children.*

In cases of purely imitative stammer in young children who are treated immediately, breathing and voice exercises with strong suggestion are sufficient to effect a rapid and permanent cure, probing into their subconsciousness being unnecessary.

A boy of 7, whom I treated, had a severe stammer. He was highly excitable, with little self-control. Though well-built, he had very poor respiratory expansion. By teaching him correct diaphragmatic breathing, giving him easy voice exercises, explaining his "fear of speech," using strong suggestion to give him confidence, and training him in self-control, he was soon absolutely cured. I had him under my direct observation all the time, this being advisable in young children, but not necessary, if older, where the patient will carry out instructions.

I would lay stress on the importance of at once treating a stammer in young children, since, if taken at an early stage, the cure is certain. Most of the adult stammerers in civil life might have been cured when young. Thus it seems apparent, in the case of adults, that to treat the symptom alone, ignoring the repressed memory or, conversely, to revive the repressed memory ignoring the symptom is, in either case, insufficient. The quickest and most permanent results being obtained by a combination of the two—i.e., "mental exploration" and re-education.

#### *WELFARE OF THE BLIND.*

THE Ministry of Health announce that they have, after consultation with the Advisory Committee on the Welfare of the Blind, issued Regulations under which, subject to the consent of Parliament, grants will be paid in aid of certain services carried on on behalf of the blind. These services include workshops, assistance to home-workers, home teaching, homes and hostels, book production, &c. In a covering letter to the regulations the needs of the unemployable blind living in their own homes are recognised as requiring legislative treatment, and it is indicated that proposals will be laid before Parliament as early as possible. The regulations have been put on sale (price 3d.) and can be obtained directly from the Stationery Office or through any bookseller.

#### *VIVISECTION EXPERIMENTS.*

A RETURN issued by the Home Office shows the number of experiments on living animals during 1918 in the United Kingdom. In England and Scotland licences were held by 701 persons, of whom 401 performed no experiments. In Ireland there were 22 licensees, of whom 6 performed no experiments. In England and Scotland the total number of experiments was 77,610; under Group A 1557, and under Group B 76,053. In Group A anaesthesia was required—951 all the time and 606 part of the time. In Group B no anaesthetic was required. They were simple inoculations, hypodermic injections, feeding, and similar proceedings. Cancer investigation accounted for 137 in Group A and 5890 in Group B; 29,000 were on behalf of Government Departments and public health authorities, and over 37,000 for the preparation, standardising, and testing of sera, vaccines, and drugs. In Ireland 313 experiments were performed by 16 licensees, of which 232 were simple inoculations.

# GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

## POWERS, DUTIES, AND CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE powers and duties of the General Medical Council, or "General Council of Medical Education and Registration of the United Kingdom" to give the Council its full title, have been set out in detail in many previous Students' Numbers of THE LANCET. It is first a registering body: no person, even though his qualifications have been obtained, is a legally qualified medical practitioner unless his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that the education of medical men is kept up to an efficient standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Fourthly, to the Council is committed the codification of pharmaceutical remedies.

The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council at present consists of 38 members, of whom, as will be seen by the annexed list, all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives.

President of the General Council: Sir Donald MacAlister. Members of the General Council: Sir Norman Moore, chosen by the Royal College of Physicians of London; Mr. Holburt Jacob Waring, Royal College of Surgeons of England; Dr. Benjamin Bloomfield Connolly, Apothecaries' Society of London; Dr. Arthur Thomson, University of Oxford; Professor Frederick Gowland Hopkins, University of Cambridge; Dr. Robert Howden, University of Durham; Dr. Sydney Russell Wells, University of London; Dr. Grafton Elliot Smith, Victoria University of Manchester; Sir Harry Gilbert Barling, University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Thomas Wardrop Griffith, University of Leeds; Mr. Rutherford John Pye-Smith, University of Sheffield; Sir Isambard Owen, University of Bristol; and Dr. David Hepburn, University of Wales. Dr. William Russell, chosen by the Royal College of Physicians of Edinburgh; Mr. James William Beaman Hodson, Royal College of Surgeons of Edinburgh; Dr. David Neilson Knox, Royal Faculty of Physicians and Surgeons of Glasgow; Dr. H. Harvey Littlejohn, University of Edinburgh; Sir Donald MacAlister, University of Glasgow; Dr. Matthew Hay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore, chosen by the Royal College of Physicians of Ireland; Sir Arthur Gerald Chance, Royal College of Surgeons in Ireland; Dr. Edward Magennis, Apothecaries' Hall of Ireland; Dr. Arthur Francis Dixon, University of Dublin; Sir Bertram Coghill Alan Windle, National University of Ireland; and Dr. Thomas Sinclair, Queen's University of Belfast. Nominated by His Majesty, with the advice of his Privy Council: Sir Charles Sissmore Tomes, Sir Arthur Newsholme, Sir Francis Henry Champneys, Dr. John Christie McVail, and Dr. Edward Coey Bigger. Elected as Direct Representatives: Dr. Langley Browne, Dr. H. A. Latimer, Dr. J. A. MacDonald, Mr. Thomas Jenner Verrall, Dr. Norman Walker, and Dr. Leonard Kidd. Treasurers of the General Council: Sir Charles Sissmore Tomes and Sir Norman Moore.

## THE EDUCATIONAL CURRICULUM.

*Professional Education.*—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

*Registration and Preliminary Examination of Medical Students.*—The following are the General Medical Council's Regulations in reference to the registration of students in medicine.

Every medical student should be registered in the manner prescribed by the General Medical Council. The registration No. 5009.

of medical students is placed under the charge of the Branch Registrars. Every person desirous of being registered as a medical student should apply to the Branch Registrar of the division of the United Kingdom in which he is residing; and should produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years, and has commenced medical study at an institution approved by the Council. The Branch Registrar shall enter the applicant's name and other particulars in the Students' Register and shall give him a certificate of such registration. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The commencement of the course of professional study recognised by any of the qualifying bodies should not be reckoned as dating earlier than 15 days before the date of registration. In addition to the universities and schools of medicine there are many institutions where medical study may be commenced. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

## *Regulations for the Maintenance of the Register of Medical Students.*

The following examinations have been approved by the Council:—(a) The final examinations for the degrees in Arts and Science of any University of the United Kingdom or of the British Dominions. (b) All examinations which are accepted for Matriculation in the Faculties of Arts and Science in any one University of Great Britain, provided the pass-certificate includes English, Mathematics, and at least two other subjects named in the following list:—Latin, Greek, Hebrew, Arabic, Persian; French, German, Spanish, Italian, Russian, or any approved modern language; History, Geography, Natural Philosophy or Physics, Chemistry, Biology, Physical Geography, and Geology. (c) All examinations not included under the foregoing section (b), which are accepted for Matriculation in the Faculty of Medicine in any one University of the United Kingdom of Great Britain and Ireland provided the examination is completed at not more than two periods of examination, and that the pass-certificate includes English, Mathematics, Latin (or Greek or Hebrew), and at least one other subject named in the following list:—Latin, Greek, Hebrew, Arabic, Persian, French, German, Spanish, Italian, Russian, or any approved modern language. (d) The Council may grant special recognition to the following examinations not included under the foregoing sections (a), (b), and (c):—(1) The final examinations for the degrees in Arts and Science of any specially recognised Foreign University. (2) Examinations conducted by approved Examining Bodies within the United Kingdom under the provisions set forth in the foregoing section (c). (3) Examinations conducted by approved Examining Bodies out of the United Kingdom under the provisions set forth in the foregoing section (c), and under such other conditions as the Council may impose in each case.

## *List of Bodies whose Examinations are accepted under the foregoing Regulations.*

### *I. Examinations in Great Britain.*

(1) The Matriculation Examinations in the Faculties of Arts and Science of, and all examinations accepted in lieu thereof by, the following Universities: Oxford (including Responsions and Moderations), Cambridge (including the Previous Examination and the General Examination), Durham, London, Manchester, Birmingham, Liverpool, Leeds, Sheffield, Bristol, Wales, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions set forth under Section 2 (b) above. (2) The Preliminary Examinations in the Faculty of Medicine of, and all examinations accepted in lieu thereof by, the Universities of Durham, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions of Section 2 (c) above. (3) Specially recognised Examinations conducted by approved bodies.

The following Schools Examinations have been recognised by the English Board of Education and are accepted by the General Medical Council under the conditions noted below.

## AS FIRST EXAMINATIONS.

1. The School Certificate Examination of the Oxford and Cambridge Schools Examination Board.
2. The Senior Local Examination of the Oxford Delegacy for Local Examinations.
3. The Senior Local Examination of the Cambridge Local Examinations and Lectures Syndicate.
4. The School Certificate Examination of the University of Bristol.
5. The First School Certificate Examination of the University of Durham.
6. The General School Examination of the University of London.
7. The School Certificate Examination of the Northern Universities Joint Matriculation Board.

## AS SECOND EXAMINATIONS.

8. The Higher Certificate Examination of the Oxford and Cambridge Schools Examination Board.
9. The Higher School Certificate Examination of the Oxford Delegacy for Local Examinations.
10. The Higher School Certificate Examination of the Cambridge Local Examinations and Lectures Syndicate.
- (a) 11. The Higher School Certificate Examination of the University of Bristol.
12. The Higher Certificate Examination of the University of Durham.
- (c) 13. The Higher School Certificate Examination of the University of London.
14. The Higher Certificate Examination of the Northern Universities Joint Matriculation Board.

(a) These Examinations will be held for the first time in 1919. In the First Examinations: School Certificates ("passes with credit") and in the Second Examinations: Higher Certificates, provide in both instances that they fulfil the conditions required for Matriculation in the Faculties of Arts or Pure Science in any University of Great Britain, are accepted by the General Medical Council under Clause 2(b); otherwise they are accepted under Clause 2(c), provided that evidence is afforded that all the subjects required by the Council have been actually passed on an approved standard. (*Applicants are advised to apply to the Examining Bodies for the necessary evidence.*)

Other Certificates accepted under Clause 2(b). Scottish Education Department: Leaving Certificates. Other certificates accepted under Clause 2(c). Intermediate Certificate. Central Welsh Board: Senior Certificate. University of St. Andrews: Final Examination for Diploma of L.L.A. College of Preceptors: Senior Certificate; Preliminary Examination for Medical Students Certificate. Educational Institute of Scotland: Preliminary Medical Examination Certificate.

## II. Irish Examinations.

University of Dublin: Matriculation Examination: (a) Junior Freshman Term Examination (exclusive of Trigonometry); (b) Special Preliminary Examination to be held in March, the standard and subjects of which shall be those of a Junior Freshman Examination (exclusive of Trigonometry); (c) Junior Exhibition Examination on obtaining marks of sufficient merit in the subjects of (a) or (b); (d) Examinations for the First, Second, Third, or Fourth Year in Arts. (Certificate to be signed in the approved form by the Medical Registrar of the University.) Queen's University of Belfast: Matriculation Examination. National University of Ireland: Matriculation Examination. Intermediate Education Board of Ireland: Middle Grade Examination, with Honours in three subjects; Senior Grade Examination. Royal Colleges of Physicians and Surgeons in Ireland: Preliminary Examination. These Examinations are accepted subject to the conditions set forth in Section 2(c) above.

The remainder of the curriculum, though all under the supervision of the Council, is in detail in the hands of the various degree- and diploma-granting bodies whose representatives are members of the General Medical Council. In the next pages we give the regulations of the various examining bodies, but it must always be remembered that the examinations are under the supervision of the General Medical Council, who visit the various centres in turn and closely inspect the procedure.

## III. Examinations Held Out of the United Kingdom

Every Certificate from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at not more than two examinations; copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classical Oriental Language (e.g., Sanskrit, Arabic, Chinese) may be accepted instead of an Examination in Latin. The German Abiturienten-Examen of the Gymnasia and Real-Schulen and the examinations entitling to the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences and other corresponding Entrance Examinations to the Universities in Europe are recognised by the General Medical Council.

These examinations are accepted subject to the conditions set forth in Section 2(c) above.

Further particulars are given in the Students' Regulations, which can be obtained at the offices of the Council, price 9d.

## The Registration of Medical Practitioners.

Under the provisions of the Medical Act, 1858, any person possessing one or other of the medical qualifications enumerated in the schedule to the Act is entitled to registration by the General Medical Council on producing to the registrar of a Branch Council proper evidence of qualification. Registration entitles him, in the words of the Act of 1886:—

"... To practise medicine, surgery, and midwifery in the United Kingdom, and (subject to any local law) in any other part of [Her] Majesty's dominions, and to recover in due course of law in respect of such practice any expenses, charges in respect of medicaments or other appliances, or any fees to which he may be entitled."

These qualifications are enumerated in the Medical Register, printed each year under the direction of the Council, and the course of study necessary to obtain each of them is duly set out in the succeeding pages.

A number of diplomas granted in British possessions and in certain foreign countries entitle the holder to registration in the colonial or foreign list respectively of the Medical Register, and therefore to practise medicine within the borders of the United Kingdom. Some account of these diplomas is given on p. 373 and following pages.

## The Officers of the Council.

Norman C. King, Registrar of the General Council and of the Branch Council for England, 44, Hallam-street, Portland-place, W. 1.—James Robertson, Registrar of the Branch Council for Scotland, 54, George-square, Edinburgh.—Richard J. E. Roe, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin. All communications should be addressed to "The Registrar" and not by name.

## POSTPONEMENT OF THE ELECTION OF DIRECT REPRESENTATIVES.

By an Order in Council dated August 14th the provisions of the Parliament and Local Elections Act, 1918, have been extended to the election of members of this Council by registered practitioners resident in the United Kingdom, the effect of which is to extend the term of office of the existing Direct Representatives until Dec. 31st, 1919.

## SCHOOLS OF THE UNITED KINGDOM.

A GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS FOR THE BRITISH MEDICAL REGISTER.

## I.—ENGLAND AND WALES.

## THE UNIVERSITIES.

## UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M. and D.M.*, two degrees in Surgery, *B.Ch. and M.Ch.*, and two diplomas, *Public Health and Ophthalmology*.

Graduates in Arts (*B.A. or M.A.*) are alone eligible for the degrees. The most convenient course for the *B.A.* degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. In order to obtain the degrees of *B.M.* and *B.Ch.* the following examinations must be passed:—1. Preliminary subjects: Mechanics and Physics, Chemistry, Zoology, and Botany. 2. Professional. (a) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology, unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy. (b) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, *Materia Medica* and Pharmacology. The approximate dates of the examinations are as follows:—Preliminaries—Zoology, Botany, and Chemistry, December and June; Mechanics and Physics, March and June; Professional (First and Second *B.M.*), June and December.

The First Examination for the degrees of *B.M.* and *B.Ch.* may be passed as soon as the Preliminary Scientific Examinations have been completed. Anatomy and Physiology are to be passed together, and Organic Chemistry may be taken before or after these have been passed.

The *Second Examination* may be passed after the completion of the first, but Pathology, Hygiene, and Materia Medica and Pharmacology may be taken before or with the remaining subjects. Before admission to the Second Examination candidates must present certificates of attendance on a course of laboratory instruction in Practical Pathology and Bacteriology and of having acted as post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also they must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, of proficiency in the practice of Vaccination and Anæsthetics, and of having attended a course of Practical Pharmacology. Also in respect of the First Examination candidates must present certificates showing that they have dissected the whole body once and have attended courses of laboratory instruction in Practical Histology and Practical Physiology.

The degree of *D.M.* is granted to Bachelors of Medicine of the University provided they have entered their thirtieth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of *B.M.* whose subject is dealt with. The degree of *M.Ch.* is granted to Bachelors of Surgery of the University who have entered their twenty-first term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed the *M.Ch.* examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second *B.M.* Examination.

*Diploma in Ophthalmology.*—The examination is held in July.

*Diploma in Public Health.*—Examinations in June and November.

*Travelling Fellowship, Scholarships, and Prizes.*—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year. The Scholarships in Science which are offered by several Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years.

In addition to the University lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the *B.A.* degree.

In the Radcliffe Infirmary and County Hospital clinical instruction is given by the Regius Professor of Medicine, the Litchfield Lecturers in Medicine and Surgery, and the other physicians and surgeons. Instruction is also given in post-mortem work and Clinical Pathology in connexion with the courses in Pathology.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1918 (both of which are published by the Clarendon Press); from the Regius Professor of Medicine; and from the Professors in the several departments of medical science. Certain special conditions as regards students who have been engaged on war service may be obtained on application to the Assistant Registrar of the University, Clarendon Building, Oxford.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lec-

turers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Practical Pharmacy is taught in the Radcliffe Dispensary. Opportunities are offered to students who wish to act as surgical dressers and clerks. The Hospital contains 170 beds.

#### UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being graduates of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing either (a) the General Examination and one Special Examination, or (b) two Special Examinations for the ordinary *B.A.* degree, or an Honours degree in one of the Triposes. The Natural Sciences Tripos is taken most frequently, as some of the subjects are practically the same as those for the first and second *M.B.*

For the degree of *Bachelor of Medicine (M.B.)* five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till he has passed, say, the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for *M.B.* Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for *M.B.* The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for *M.B.* The first includes (1) Chemistry and other branches of Physics, and (2) Elementary Biology. These parts may be taken together or separately. The second is divided into two parts—viz., (1) Human Anatomy and Physiology; and (2) Pharmacology and General Pathology. The third is also divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic.

Candidates who have passed both parts of the third *M.B.* examination are admitted to the registrable degree of *Bachelor of Surgery (B.Ch.)* without separate examination and without keeping an Act.

The degree of *Doctor of Medicine (M.D.)* may be taken three years after that of *M.B.* or four years after that of *M.A.* The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an *M.A.*, to pass the same examinations as are required for the degree of *M.B.* An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *viva voce* examination; and a short

extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery (M.Ch.)* the candidate must have passed all the examinations for B.Ch., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required either (1) to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject; or (2) to submit to the Medical Board original contributions to the advancement of the Science or Art of Surgery. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Ch. Before submitting original contributions he must have been qualified at least three years.

**Women Students.**—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the First and Second M.B. Examinations under certain conditions.

**University Prize in Medicine.**—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical Studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registry, the Registry, Cambridge.

**ADDENBROOKE'S HOSPITAL.**—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term. All communications by students should be made to Dr. Aldren Wright.

#### UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament 1898 and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Teachers were also appointed in special subjects to give lectures at the University.

**Teaching Staff.**—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by, and are paid out of the funds of, the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective medical schools.

**Internal and External Students.**—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (a) under the direct control of the University or a committee appointed thereby; or (b) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by

the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Gny's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other universities and medical schools, presenting themselves for examination at the University of London.

**Faculty of Medicine.**—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), and the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*).

The curriculum for the Bachelor's degrees is now five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W. 7, and the examinations formerly known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees. Part II. of the former Preliminary Scientific Examination has now been made Part I. of the Second Examination.

**A. Internal Students.**—In order to be admitted to the Bachelor's degrees a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (a) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, and General Biology; (b) the Second Examination for Medical Degrees: Part I., Organic and Applied Chemistry; Part II., Anatomy, Physiology, and Pharmacology, including Pharmacy and Materia Medica; (c) the Third Examination for Medical Degrees, or M.B., B.S. Examination: Medicine and Surgery, Midwifery and Diseases of Women, Pathology, Forensic Medicine and Hygiene.

**B. External Students.**—To be admitted to the Bachelor's degrees an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more of the recognised institutions or schools in the United Kingdom.

**The First Examination for Medical Degrees (Inorganic Chemistry, Physics, and General Biology)** will take place twice in each year, commencing on the Monday following Dec. 7th and on the second Monday in July. It must as a rule be passed not less than nine months after matriculation.

**The Second Examination for Medical Degrees (Part I.): Organic and Applied Chemistry.**—This examination will take place twice in each year, commencing on the Wednesday following the third Monday in March and on the afternoon of the Thursday following the second Monday in July. No candidate will be admitted to this examination within six months of having passed the First Examination.

**The Second Examination for Medical Degrees (Part II.)** takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. The subjects of the examination are Anatomy, Physiology, and Pharmacology, including Pharmacy and Materia Medica. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

*The Third or M.B., B.S. Examination.*—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination, for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part. II. (1) Principles and Practice of Medicine; (2) Clinical Methods and Physical Diagnosis; (3) Insanity (with clinical demonstrations at a recognised Asylum); (4) Therapeutics; (5) Vaccination; (6) Principles and Practice of Surgery; (7) Operative Surgery, Surgical Anatomy, Practical Surgery, and the Administration of Anæsthetics; (8) Diseases of the Eye, Ear, Throat, and Skin; (9) Lectures and Demonstrations on Midwifery and Diseases of Women; (10) Practical Midwifery, the conduct of at least 20 Labours, and practice as a Clinical clerk in Gynæcological work; (11) Pathology and Bacteriology; (12) work of the Post-mortem room; (13) Forensic Medicine; and (14) Hygiene. He must also have attended the Medical and Surgical practice of a recognised hospital for two years and a course of instruction at a recognised Fever Hospital for two months. He must have had clinical instruction and must have held the posts of medical clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

*Doctor of Medicine.*—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

*Master in Surgery.*—The examination for the degree of Master in Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July.

*Fees.*—Matriculation £2 2s. for each entry. At provincial examinations an additional local fee is charged. First examination for Medical Degrees: £5 5s. for each entry to the entire examination. For re-examination in one subject the fee is £2 2s. In the second examination, Part I. £2 2s., repeated on each subsequent entry; Part II. £8 8s. for the whole examination. Third examination: £10 10s. for each entry to the whole examination. M.D. Examination: £21; for re-examination £10 10s. M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Principal Officer, University of London, South Kensington, S.W.

## MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.<sup>1</sup>

**ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.**—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. It receives over 8000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopaedic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical

operations take place every day at 1.30 P.M. and Surgical Consultations are held on Thursdays at the same hour. Medical Consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical Lectures on all special subjects are also given. The visits of the physicians and surgeons are made at 1.30.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident anaesthetists are appointed annually, and receive salaries of £120, £100, and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

*New Buildings.*—The new buildings comprise residential quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. A new chemical laboratory has been added to the Medical School, and a laboratory devoted to instruction in Public Health. A second new block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, pathological histology, and pathological chemistry. *The Medical School Buildings* include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

*Special Classes* for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. *Laboratory Instruction for the D.P.H.* is provided during the winter and summer sessions.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

*Scholarships given in aid of Medical Study.*—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (a), (b), two Entrance Scholarships of the respective values of £75 and £100; (c) Entrance Scholarship in Arts, £100; (d) Jeaffreson Exhibition, £50; and (e) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (a), and (b) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, and Anatomy; (c) and (d) are awarded after examination in Latin, Mathematics, and Greek or French or German; (e) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The remaining Scholarships and prizes are as follows:—Four Junior Scholarships: (f) No. 1, £30, Anatomy and Physiology; (g) No. 2, £20, Anatomy and Physiology; (h) No. 3, £25, Chemistry, Physics, and Biology; (i) No. 4, £15, Chemistry, Physics, and Biology; (j) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (k) Kirkes Scholarship, £30 and medal, Clinical Medicine; (l) and (m) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (n) Sir G. Burrows Prize, £10, Pathology; (o) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (p) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (q) Luther Holden Research Scholarship in Surgery, awarded by election, £105; and (r) Lawrence Research Scholarship and gold medal in Pathology, awarded by election, £115.

<sup>1</sup> For Ancillary Metropolitan Medical Schools see p. 376.

Information may be obtained on application to the Dean of the Medical School: Dr. T. W. Shore. The Warden of the College is Mr. W. Girling Ball.

**CHARING CROSS HOSPITAL.**—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Eye, Ear, Throat, Nose, and Teeth, for Orthopaedic Cases, X Ray work, and for Electrical Examination and Treatment.

**Appointments.**—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year after competitive examination.

**Primary and Intermediate Studies.**—By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk. This arrangement has proved most successful.

**Final Studies.**—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of *Materia Medica*, *Toxicology*, and *Operative Surgery*.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School. Students receive their training in Preventive Medicine, Pathology, and Bacteriology here, and are encouraged to undertake Research. Special facilities for Post-graduate Research and Study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Special lectures and demonstrations are arranged for Post-graduates.

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynaecological specimens, "The Cuthbert Lockyer Collection."

**Students' Club.**—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c. The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society.

**Women Students.**—Women students are accepted by the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments. A separate common-room and a female attendant are provided, but beyond this no further distinction is made. This system of co-education, under which men and women are placed on terms of complete equality throughout the whole of the curriculum, has been found to work successfully and to their mutual advantage.

**Fees.**—An entrance fee of 10 guineas and 8 guineas is payable by full-course and final-course students respectively, and an annual fee of 26 guineas covers all other expenditure, with the exception of 7 guineas for vaccination, dispensing, and fever hospital attendance, which must be taken outside the hospital. Membership of the Students' Club is included in these fees.

Further information may be obtained on application to the Dean, Dr. W. J. Fenton, Medical School, Charing Cross Hospital, London, W.C.

**ST. GEORGE'S HOSPITAL.**—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for Diseases Peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

Entrance Scholarships and Endowed Prizes of a total value of £576 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the University of London for students who enter during the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at either University College or King's College. Students then complete their course,

without payment of any entrance fee, in a school entirely devoted to Clinical work.

Eight house physicians and eight house surgeons are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anaesthetist at £100; the post of Senior Anaesthetist at £50; the posts (3) of Junior Anaesthetists, each at £30. The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the chess, lawn tennis, boxing, hockey, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

**Scholarships and Prizes.**—At this school two entrance scholarships are given, the money value and the subjects of examination being as follows: (a) and (b) two University Entrance Scholarships, 70 guineas and £50 respectively, Anatomy and Physiology. The others are as follows: (c) William Brown Exhibition, tenable for two years and open to perpetual pupils having registrable qualifications, £135 per annum, Practice of Medicine, Midwifery, and Surgery; (d) William Brown Exhibition, tenable for three years and open to perpetual pupils qualified not more than three years previously, £45 per annum, Essay and Original Work; (e) Allingham Scholarship in Surgery for Students qualified not more than three years, £60, Competitive Essay; (f) and (g) two Brackenbury Prizes, one in Medicine and one in Surgery, £30 each, open to students of not more than five years' standing; (h) H. C. Johnson Memorial Prize, £15, Practical Anatomy; (i) Pollock Prize, £17, Physiology, Physiological Chemistry, and Histology; (j) Clarke Prize, £5; (k) Thompson Medal, £5, Clinical Reports; (l) Brodie Prize, £7, Clinical Reports; (m) Webb Prize, open to perpetual pupils, £30, Bacteriology; (n) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications.

Further information may be obtained from the Acting Dean of the Medical School, Mr. R. R. James.

**GUY'S HOSPITAL.**—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 644 beds. The school buildings have been rebuilt and now offer very complete accommodation. Within the grounds of the hospital are situated the residential college, with accommodation for 60 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anaesthetists, surgeons' dressers, medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit.

There is a Medical Section of the Officers' Training Corps of the University of London in connexion with the Hospital. Drill is held in the grounds of the Hospital, so that the senior students can carry out the necessary military training without any serious interruption of their work in the wards. The establishment of a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee. Residential College: the rent of rooms remains the same, but the cost of board has increased.

**Scholarships.**—Five entrance scholarships are awarded annually as follows:—(a) one scholarship of £100 for students under 21 years of age, Latin, English, Greek or French or German, Arithmetic, Euclid, and Algebra; (b) one scholarship for students under 21 years, £120,

Inorganic Chemistry, Physics, and Biology; (e) a Scholarship of £50, open to candidates under 21 years of age, to be awarded either in Arts or in Science, according to the discretion of the Examiners, and to the percentage of the marks obtained; (d) two scholarships, one of £75 and one of £35, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire. Subjects: Any two of the following: Anatomy, Physiology, Pharmacology, General Pathology, Organic Chemistry.

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates, the term "military service" meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the war; or (2) in respect of other approved duties in connexion with national defence.

The Dean of the Medical School is L. Bromley, M.Ch., from whom further information may be obtained.

**UNIVERSITY OF LONDON: KING'S COLLEGE.**—The medical department (Faculty of Science, Medical Division) at this College only deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants. The following four hospital schools prepare their students only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital—sending them to King's College for the earlier part of the curriculum. The department is open to both men and women.

**Fees.**—For London University course: For First examination for medical degrees, 25 guineas; for the Second examination, 58 guineas, or two instalments of 30 guineas each. For Conjoint Board course: For First examination, 20 guineas; for Second examination, 58 guineas, or two instalments of 30 guineas each. For prospectus and further information application should be made to the Dean of the department (Professor W. D. Halliburton).

**KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.**—The advanced subjects in the curriculum are dealt with at the Medical School attached to King's College Hospital, which is situated at Denmark Hill, S.E. The hospital stands in the midst of a South London population, from which an immense amount of clinical material is forthcoming, an average of 3500 out-patients being dealt with weekly. There are 400 beds available for in-patients, and provision will ultimately be made for 600 beds. Special departments are provided for the following: diseases of women and children, the eye, ear, throat and nose, skin, teeth; radiography, radiotherapy and radium-therapy; pathology, massage, medical gymnastics, and electro-therapeutics. The appointments open to students are those of senior clinical assistant to the special departments; medical, surgical, and obstetric tutors; resident casualty officer; resident anaesthetist; resident assistant pathologist; and medical, surgical, and obstetric registrarships. There are 16 resident medical and surgical officers appointed yearly.

**Scholarships and Prizes.**—For the first two scholarships in the list here shown a complete course at King's College is required. The money value and subjects of examination are as follows:—(a) Two Warneford Scholarships, tenable for four years, £25 each per annum; (b) Sambrooke Scholarship, £50; (c) Rabbeth Scholarship, £20; (d) Medical Entrance Scholarships, £50, Anatomy and Physiology, and, £50, Pathology and Pharmacology, open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (e) Two Medical Entrance Scholarships one in Arts and one in Science, £50 each, tenable for five years, successful candidates to study at King's College and King's College Hospital; (f) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (g) Two Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital, £50 each; (h) Carter Prize, £15, Botany; (i) Tanner Prize, £10, Obstetrics and Diseases of Women; (j) Todd Prize, £4 4s. and medal, Clinical Medicine; (k) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge.

**Athletics.**—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. Admirable playing fields, over six acres in extent, have been provided for the use of the students on Dog Kennel Hill, Lordship-lane, S.E., about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Plantans," the hall of residence for students belonging to the hospital.

**Fees.**—The composition fee for Hospital work and Final subjects of the curriculum is 70 guineas if paid in one sum, or 72 guineas if paid in two instalments, in addition to the Entrance Fee of 10 guineas. For information and prospectus application should be made to either of the following: H. Willoughby Lyle, M.D. Lond., F.R.C.S., Dean; S. C. Ranner, M.A. Cantab., Secretary of the Medical School, King's College Hospital, Denmark Hill, S.E. 5.

**LONDON HOSPITAL.**—The hospital, with its Medical College and Dental School, is situated in the Mile End-road, E. The hospital contains 933 beds, which are in constant use, and is the only general hospital for East London. During last year 17,247 in-patients and 94,554 out-patients received treatment, while 9056 major operations were performed. 26,319 out-patients attended the special departments of the Ear, Nose, Throat, Skin, Teeth, &c., and the Obstetric, Orthopaedic, and Venereal Departments. The hospital presents, therefore, a large field for clinical instruction, and in its Wards and Out-patient Departments exceptional opportunities are offered for acquiring an extensive and practical experience of all phases of disease. Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital. Holders of resident appointments have free board. Special classes are held for the degrees of the University of London, the Fellowship of the Royal College of Surgeons, and other higher examinations. Special entries for medical and surgical practice can be made. A residential Hostel on hospital grounds is provided for the convenience of students. The Clubs Union Athletic Ground is within easy reach of the hospital.

**Scholarships and Prizes.**—At this school the successful candidates for the first items in the list here shown must enter as full students. The value and the subjects of examination are as follows:—Price Scholarship £100; and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarship, open to students of Oxford and Cambridge Universities, £52 10s., Human Anatomy and Physiology; Buxton Scholarship, £31 10s., subjects of Anatomy and Physiology; three Scholarships for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Pathology, Practical Medicine, and Surgery; Letheby Prizes (2), £25, Chemistry; eight Dressers' Prizes, amounting to £40, zeal, efficiency, and knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £40, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology; James Anderson Prizes, £9, Elementary Clinical Medicine; Forensic Medicine; Arnold Thompson Prize, £15; Wynne Baxter Prize, £5 5s.; and Liddle Prize, triennial, £120.

**Medical Research Funds.**—Research Funds of over £25,000, including the Eliza Ann Alston Endowment Fund for Medical Research, provide valuable scholarships for men wishing to undertake research or desirous of preparing Theses for University degrees.

The Schorstein Memorial lectures in Clinical Medicine, which have been postponed during the war, will be given during 1919-20 by Sir Archibald E. Garrod, K.C.M.G., F.R.S., physician to St. Bartholomew's Hospital.

**ST. MARY'S HOSPITAL.**—305 beds. The number of in-patients treated during 1918 was 3034. The number of out-patients was 11,346 with 19,145 casualty cases, a total of 30,491. The situation of the hospital and Medical School in the centre of the residential districts of Paddington, Bayswater, and North Kensington renders it exceptionally convenient for students' rooms, a register of which is kept by the authorities for the use of students.

*Laboratories, &c.*—The Medical School provides for the entire curriculum. Special laboratories are in use for Biology, Chemistry, and Physics, a series of lecture theatres and laboratories for Anatomy and Physiology, and a spacious and well-lighted dissecting-room. The Pathological Department is under the direction of Dr. B. H. Spilsbury, and a block of consulting-rooms and laboratories in the New Wing of the Hospital has been equipped for the department of Therapeutic Inoculation.

*Appointments.*—All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers are appointed in each year and receive board and lodging in the hospital. Two resident anaesthetists are appointed in each year and receive a salary at the rate of £100 per annum, with board and lodging. Four casualty house surgeons are appointed in each year upon the same conditions. Several assistants in the department of Therapeutic Inoculation are appointed annually at salaries of £100 per annum and upwards. In addition to the above, the senior appointments, medical, surgical, and obstetric registrar, casualty physician, demonstrator of anatomy, physiology, and biology, are made annually.

*Clubs, &c.*—The amalgamated clubs include all the various athletic clubs, as well as the medical society, &c. There is a students' club on the Hospital premises, the membership of which is included in the amalgamated clubs. The athletic clubs' ground at Park Royal, Acton, has been commandeered by the War Office and sold. Steps are now being taken to procure a new site.

*Special Tuition.*—Special tuition is provided for the Intermediate and Final Examinations of the Universities of Oxford, Cambridge, and London, and for the Primary and Final F.R.C.S.

The composition fee for full students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in Anatomy and Physiology are admitted on payment of a composition fee of 65 guineas (£68 5s.) paid in one sum or by payment of two annual instalments of 40 guineas (£42) and 30 guineas (£31 10s.) respectively. A system of annual fees is also in force as an alternative to composition fees. Separate courses of lectures, laboratory work, or hospital practice may be taken.

*Scholarships and Prizes.*—The money value and subjects of examination of these are as follows: (a) and (b) Entrance Scholarships in Natural Science, £100 and £50 respectively, awarded by competition in September; (c) the Frederic John Palmer Scholarship in Natural Science, £25; (d) University Scholarship in Natural Science, open to members of Oxford or Cambridge University, £52 10s.; (e) University Scholarship in Natural Science, open to members of any British University, £52 10s.; (f) Epsom Scholarship, awarded by nomination, £52 10s.; (g) Gold Medal, £20, an Essay on Some Special Point in Clinical Medicine; (h) Meadows' Prize, awarded in alternate years, £8, Obstetrics; (i) Wallace Memorial Prize and Medal, for work in Vaccine Therapy, £5 5s.; (j) David Lees Prize in Clinical Medicine, £8.

Sir John Broadbent is Dean of the Medical School. The School Calendar and full information can be obtained from the Secretary, Mr. B. E. Matthews, St. Mary's Hospital Medical School, Paddington, W.

**MIDDLESEX HOSPITAL.**—The Hospital and Medical School are situated in Mortimer-street, at the top of Berners-street, and only a few minutes' walk from Goodge-street Station (Hampstead and Charing Cross Tube), Oxford Circus Stations (Bakerloo and Central London Tubes), and Great Portland-street Station (Metropolitan Railway).

The hospital contains 455 beds, including special wards for Cancer Cases, Maternity and Gynaecological Cases, and for Diseases of Children and the Skin and Eye.

The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects.

In the Electro-Therapeutic Department students obtain instruction in the Treatment of Lupus and Cancer by the X Ray method of treatment. An Electrocardiograph Department has recently been established.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects of

the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly, commencing in April and October. Ample laboratory and class-room accommodation is provided.

The Bland-Sutton Institute of Pathology contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories where every facility is given for original research. The Anatomical and Pathological Museum is now part of the Institute.

Special classes are held to prepare students for the Intermediate examinations of the Universities, and for the Primary and Final examinations for the F.R.C.S. (England) Diploma. There is a Residential College in the hospital for students.

*Hospital Appointments.*—All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynaecological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anaesthetist, and two resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. The medical, surgical, and obstetric and gynaecological registrars are appointed as vacancies arise.

Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

*Scholarships, Prizes, &c.*—(a), (b), and (c) Three Entrance Scholarships, value £100, £50, and £25, and (d) a University Scholarship, value £50, are awarded annually in September. The successful candidates are required to become general students of the school. (e) A Freer Lucas Scholarship for Students of Epsom College is awarded annually on the nomination of the Headmaster. There are also, (f) and (g), two Brodrip Scholarships, value £60 and £40 respectively; (h) the Lycl Gold Medal and Scholarship, value £55 5s.; (i) the John Murray Medal and Scholarship, value £25 (awarded every third year); (k) the Freeman Scholarship, value £30; (l) the Hetley Clinical Prize, value £25; (m) the Leopold Hudson Prize, value 11 guineas; and (n) the Second Year's Exhibition, value 10 guineas. There are also numerous class prize examinations.

In connexion with the Cancer Investigation Department the following Scholarships are awarded:—Richard Hollins Research Scholarship, value £100; Walter Emden Scholarship, value £100; and a Cancer Research Scholarship, value £60.

*Fees.*—The fees are arranged on a basis of an annual payment of £30 for the five years of the curriculum. After five years, if the student is not qualified, the annual fee is £20.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, the cricket club, the football clubs, the athletic club, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. A subscription to the Amalgamated Students' Club is payable by all General and Dental students.

**ST. THOMAS'S HOSPITAL.**—This hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 1014 beds, including 530 for military patients. The in-patients last year numbered 9780, whilst the number of attendances as out-patients, including the casualty and light departments, was 242,686. There are special departments for the treatment of women, children, the eye, ear, nose and throat, skin, and teeth. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for light treatment, X rays, and the Physio-therapeutic Department are also special features. A speech clinic has recently been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of general pathology, clinical pathology, chemical pathology, cardiology, and of treatment by serums and vaccines. Surgical operations take place in the main theatres every day except Saturdays at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week.

Clinical lectures are delivered every Wednesday during the sessions. All appointments in the hospital are open to students without extra fee. Clinical assistants to all the special departments are appointed every three months. A resident assistant physician and a resident assistant surgeon, at a salary of £150 each, are appointed biennially; also four hospital registrars (medical, surgical, obstetric, and ophthalmic), the two former receive a salary of £150 and the two latter £50. An assistant in the clinical laboratory and an assistant pathologist are paid at the rate of £200 per annum. Appointments open to students before qualification: Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third year's work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anaesthetics by one of the hospital anaesthetists. The Students' Club comprises a spacious restaurant and smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

*Fees.*—The annual composition fee is 30 guineas, covering all tutorial classes—in addition to a fee on entrance. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the secretary.

*Scholarships and Prizes.*—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first medical examination; two in Natural Science, of the value of £150 and £60 respectively, to be taken out in tuition fees; and the University Scholarship of £50 in Anatomy, Physiology, and Chemistry. The money value and subjects of examination of the remainder are as follows: (a) and (b) two College Prizes, one for second-year students and one for third-year students, £10 and £5 respectively; (c) William Tite Scholarship for second-year students, £25; (d) and (e) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (f) three College Prizes for fifth-year students of £10 each and three of £5 each; (g) Cheselden Medal, Surgery and Anatomy; (h) Mead Medal, Medicine, Pathology, and Hygiene; (i) Toller Prize, Medicine, Pathology, and Hygiene; (j) Bristowe Medal, Pathology and Morbid Anatomy; (k) Solly Medal and Prize, biennially, Surgical Reports; (l) Treasurer's Gold Medal for the most distinguished fifth-year student; (m) Wainwright Prize, Medicine, Pathology, and Hygiene; (n) Hadden Prize, Pathology; (o) Beane Scholarship, £50 biennially, Surgery and Surgical Pathology; (p) Sutton Sams Prize, biennially, reports of cases in Obstetric Medicine; (q) Grainger Testimonial Prize, £31 10s. Anatomy and Physiology; (r) Salters' Company Research Fellowship, tenable for three years, £100 annually, Pharmacology; (s) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; and (t) Research Scholarship, tenable for two years, £200 per annum.

The Dean of the Medical School is Sir Cuthbert S. Wallace, the Sub-Dean Dr. C. R. Box, and the Secretary Dr. A. Elliot, from whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Physiology, and Pharmacology (the Intermediate Medical Sciences), and the Department of Hygiene and Public Health (Post-graduate Study).

*Faculty of Medical Sciences.—Composition fees.*—For the courses required by the University of London. 1. For

the First Medical Course, 26 guineas, entitling to one attendance and to the privileges of the Union Society for one session. 2. For the Second Medical (Intermediate) Course, 58 guineas if paid in one sum; 60 guineas if paid in two instalments of 30 guineas each. This fee entitles to attendance at Anatomy and Physiology during three years and to one attendance at Organic and Applied Chemistry, Pharmacology, and Materia Medica, and to the privileges of the Union Society for two sessions.

For the medical education required by the Examining Board in England and the Society of Apothecaries. First examination, Parts I., II., III., 21 guineas, entitling to attendance for the First and Second Terms and to the privileges of the Union Society for one session; 26 guineas, entitling to attendance throughout the session and to the privileges of the Union Society for one session. First Examination, Part IV., and second examination, 58 guineas if paid in one sum, and 60 guineas if paid in two instalments of 30 guineas each. This fee entitles to attendance during three years in all subjects but Practical Pharmacy and to the privileges of the Union Society for two sessions.

*Scholarships and Prizes.*—The first three items on the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (a) The Bucknill Scholarship, 135 guineas; (b) and (c) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (d) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, and Chemistry; (e) Schäfer Prize in Physiology, £18 triennially; (f) Sharpey Physiological Scholarship, £105, Biological Sciences; (g) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £16 a year; and (h) five Gold and five Silver Medals awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Dean: Dr. G. F. Blacker. Acting Secretary: G. E. Adams. Open to men and women students. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B.S. (London) Course, 80 guineas if paid in one sum, 82 guineas if paid in two instalments, as follows—first year, 50 guineas; second year, 32 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham, and for the medical education required by the Examining Board in England and the Society of Apothecaries.

There are over 300 beds in the hospital.

*Special Departments, Clinical and Laboratory Facilities.*—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. Special courses of Lectures and Demonstrations in Anaesthetics, Diseases of the Eye, of the Ear, Nose, and Throat, and of the Skin, in Electrical and Radioscopic Diagnosis and Treatment, and in Clinical and Cardiac Pathology are also given. These courses are designed for senior students and graduates. Special arrangements have been made which enable students of University College Hospital to carry out a portion of their clinical studies at the National Hospital for Nervous Diseases, Queen-square, the Children's Hospital, Great Ormond-street, and the Central London Ophthalmic Hospital, Judd-street. The Royal Ear Hospital, Dean-street, Soho, has been amalgamated with University College Hospital as the Ear, Nose and Throat Department. In the Dental Department in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

*Appointments tenable by Students.*—Clerkships and dresser-ships to the physicians, surgeons, anaesthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Eight house physicians and house surgeons, four senior and four junior obstetric assistants, are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: 1. The Resident Medical Officer. This officer is appointed for a period of two years and is chosen from amongst the more senior recent residents of the hospital. 2. The two Surgical Registrars are also chosen from among the more senior recent residents of the hospital. 3. The Obstetric Registrar. 4. Two Casualty Medical Officers and a Casualty Surgical Officer are appointed, each for a period of six months. 5. Assistant in Ear and Throat Department, appointed for one year. 6. Assistant in Ophthalmic Department, appointed for one year. 7. Registrar in Anaesthetic Department, appointed for one year. 8. Deputy Anaesthetists. During the absence of one or another of the Anaesthetists in the summer months a senior qualified student is appointed as a substitute and is granted a special certificate.

*Museum of Pathological Anatomy.*—The Museum is open for study from 9 A.M. to 5 P.M. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 13,500 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of Medical and Surgical Science, and (2) of promoting social intercourse among its members. All Students of the Medical School are eligible for membership. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London University College, is situated near the Great Western Railway station at Perivale.

*Scholarships and Prizes.*—At this School the first two Scholarships (a) and (b) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (c) and (d) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(a) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (b) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (c) and (d) two Goldsmid Entrance Exhibitions, 80 guineas each, Anatomy and Physiology; (e) Graham Scholarship in Pathology, £200 per annum for two years, awarded by the Senate of the University of London; (f) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (g) Atchison Scholarship, tenable for two years, £55 per annum; General Proficiency in Medical Studies; (h) Magrath Clinical Scholarship, about £100, Clinical Cases; (i) Percival Alleyn Scholarship, about £60, Surgery; (j) Filliter Exhibition, £30, Pathology; (k) Erichsen Prize, £10 10s., Practical Surgery; (l) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (m) two Liston Gold Medals for Clinical Surgery; (n) Alexander Bruce Gold Medal for Pathology and

Surgery; and (o) Tuke Silver and Bronze Medals for Pathology. (p) Radcliffe Crocker Travelling Scholarship for Dermatology. (q) Leslie Pearce Gould Travelling Scholarship for Surgery.

*Residence of Students.*—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers.

**WESTMINSTER HOSPITAL.**—The hospital contains 215 beds and affords relief to upwards of 2000 in-patients and 30,000 out-patients annually. There are separate departments for Diseases of the Eye, Ear, Skinf, Teeth, and Throat, for Orthopaedic practice, for Diseases of Women, for Diseases of Children, for Radiography, and for the Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments will be made as soon after the conclusion of the war as possible.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore.

*Scholarships and Prizes.*—The following Entrance Scholarships are offered for competition: Winter Session: (a) Arts Scholarship, the "Guthrie," £60. (b) Science Scholarships: Natural Science Scholarship, £60; Chemistry and Physics Scholarship, £30; and Two Scholarships in Anatomy and Physiology, £50 each. Summer Session: Two Scholarships in Anatomy and Physiology, £50 each. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Notes of Cases; Clinical Surgery Prize, £5, Notes of Cases; Chadwick Prize £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship, £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, tenable for two years, £20, Chemistry; Rabbeth Scholarship, open to First-year Students, £20, Class Examinations in the Preliminary Scientific Course; and the Sambrooke King's College Scholarship in Science, value £25.

The Dean is Dr. David de Souza, to whom inquiries may be addressed.

**LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN,** 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £169 in one sum, or £179 in five instalments. These sums include library and laboratory fees.

The Royal Free Hospital contains 230 beds. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, and Brompton Chest Hospital.

An agreement has been made under which students of the school attend full clinical courses at St. Mary's Hospital, Paddington (305 beds).

Special courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental

students in conjunction with the London Dental Hospital, Leicester-square, and the National Dental Hospital.

Students after qualification can hold the posts of house physician, house surgeon, obstetric assistants, clinical assistants, assistant anaesthetist, medical, gynaecological, and surgical registrars, assistant pathologist, and museum curator; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies at the School.

*Scholarships and Prizes.*—(a) Isabel Thorne Scholarship, £30. (b) St Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (c) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years and next to be awarded in 1921. (d) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1923, £60. (e) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (f) Sir Owen Roberts Scholarship, £75 a year for four years. (g) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (h) Fanny Butler Scholarship, tenable for four years; next award in July, 1922, £14 10s. (i) John Byron Bursary, tenable from two to four years, for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st; next award in March, 1921, £20. (k) Ellen Walker Bursary tenable for two years, awarded to a student beginning fourth year of medical study, £25 a year. (l) Helen Prideaux Scholarship, awarded every second year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £40. (m) Agnes Guthrie Bursary, value £50, is offered annually to students who desire to pursue a full course of study for the Licentiate in Dental Surgery. (n) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £40, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (o) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1921. (p) Dr. Margaret Todd Scholarship, tenable for four years, £37 10s. a year, awarded in alternate years; next award in July, 1921. (q) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1920. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2s. and £1 1s. are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5s., is awarded yearly. The Edith Pechey Phipson Prize in Pharmacology, value £3 3s., is awarded annually. There is also a small loan fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help. Prizes and Certificates of Honour are awarded in each class at the end of the session.

The Dean of the Medical School is Miss Aldrich-Blake, M.D., M.S.; the Honorary Secretary, Dr. May Thorne; and the Warden and Secretary, Miss L. M. Brooks, to whom inquiries may be addressed.

#### UNIVERSITY OF DURHAM.

Two Diplomas, one Licence, and six degrees are conferred—viz., the Diploma in Public Health, Diploma in Psychiatry, the Licence in Dental Surgery, and the degrees of Bachelor of Medicine, Bachelor of Surgery, Master of Surgery, Doctor of Medicine, Bachelor of Hygiene, and Doctor of Hygiene.

For the degree of *Bachelor of Medicine* there are four professional examinations. The subjects of the

First Examination are—Elementary Anatomy, Elementary Biology, Chemistry, and Physics. The subjects of the Second Examination are—Anatomy and Physiology. The subjects for the Third Examination are—Materia Medica and Pharmacy, Pathology, Medical Jurisprudence, Public Health, and Pathology and Elementary Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Gynaecology, Therapeutics, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children.

It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor of Surgery* every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham and must have attended one course of lectures on Operative Surgery and one course on Applied Anatomy. Candidates will be required to perform operations on the dead body and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age and must satisfy the University as to knowledge of Greek or German. If he has not already satisfied the Matriculation Examiners in either Greek or German he must pass in one of these subjects at one of the ordinary matriculation examinations of the Newcastle division of the University. He must also have obtained the degree of Bachelor of Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor of Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree must present an essay. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

*Doctor of Medicine* (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees, diplomas or licence, must give at least 28 days' notice to Professor Howden, Secretary, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays six weeks before the date of the examination.

*Scholarships and Prizes.*—In connexion with this University the following Scholarships and prizes are awarded:—(a), (b), (c), and (d). Four Scholarships of £25 a year each, tenable for four years; the examination will be the September Matriculation Examination. Candidates must take English, Latin, Arithmetic, Euclid, Algebra, Geography, English History, and one, or two, of the three languages—French, Greek, German. (See College Calendar for special books.) Open to candidates desirous of being admitted as Medical Students. The successful candidates must take out their entire curriculum at the University of Durham College of Medicine, Newcastle-upon-Tyne. (e) Pears Scholarship of £50 a year (when vacant), tenable for three years; Matriculation Examination.—At the College of Medicine are: (f) Dickinson Scholarship, interest on £400 and gold medal; examination in Medicine, Surgery, Midwifery, and Pathology. Open to full students of the College of Medicine who have passed the third M.B. Examination. (g) Tulloch Scholarship, interest on £400; examination in Elementary Anatomy, Biology, Chemistry, and Physics. (h) Charlton Memorial Scholarship, interest on £700; examination in Medicine. Open to full students of the College entered for the class on the

Principles and Practice of Medicine. (i) Gibb Scholarship, interest on £500; awarded annually as a Scholarship in Pathology to full student who passes the best examination in that subject. No student is eligible after completion of his curriculum. (j) Luke Armstrong Memorial Scholarship, interest on £680: Original Essay on some subject in Comparative Pathology. (If no essay of sufficient merit be presented the scholarship may be awarded to the candidate who, in passing the first part of the Examination for the B.Hy. Degree, obtains the highest number of marks in Comparative Pathology during the year.) Open to all Graduates in Medicine or Hygiene and candidates for these degrees who have spent six months at the University and whose age does not exceed 30 years. (k) Stephen Scott Scholarship, interest on £1000; Original Essay on any Surgical subject. Open to any graduate in Medicine or Surgery of the University or any student of the College of Medicine. Student's age must not exceed 30 years. (l) Heath Scholarship in Surgery, of the value of £200, awarded every second year. All Graduates in Medicine or Surgery of the University are eligible. (m) Philipson Scholarships (2). The interest on £1800 to the candidates who obtain the highest marks in the Final M.B. Examinations held in March and June respectively. (n) Gibson Prize, interest on £250 stock; examination in subject of Midwifery and Diseases of Women and Children. Open to students who have attended one course of lectures on Midwifery and Gynaecology. (o) Outtersen-Wood Prize, interest on £250, in Psychological Medicine. (p) Turnbull Prize and Medal; examination in Surface Anatomy. Open to students at end of their second winter session.—At the Royal Infirmary is (q) Goyder Memorial Scholarship, interest on £325; awarded annually to student who most distinguishes himself in Clinical Medicine and Clinical Surgery at the Royal Infirmary. For further information apply to Professor R. Howden, Secretary of the College.

*Hygiene.*—The regulations with regard to the degrees in Sanitary Science will be found under the section on Public Health.

THE COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—Clinical instruction is given at the Royal Victoria Infirmary, containing 600 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII. in 1906. The number of beds is 585. The number of in-patients annually is 9200 and of out-patients 69,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians, Assistant Surgeons, and Surgical Registrars weekly, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynaecological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The surgical practice is especially good. The session opens on April 17th and Oct. 2nd of each year. Applications for detailed information should be made to the Dean, Dr. Horsley Drummond, at the hospital.

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological

Medicine at the Sunderland Mental Hospital, Ryhope. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is further taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye. Secretary: Mr. Richard Smith, 61, Westgate-road, Newcastle-on-Tyne.

#### UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other school or schools of medicine recognised by the University. The students of the Medical Faculty can be members of the University Club, the University Athletic Club, and the University Officers' Training Corps, while they possess a guild—the Guild of Undergraduates—which is designed to be a recognised medium of communication between the teachers and the taught. The University Medical Society and the Dental Students' Society also offer opportunities of coöperation for mutual benefit.

*Degrees of Bachelor of Medicine and Bachelor of Surgery.*—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary to the Board, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Chemistry and Physics and Elementary Biology. Second Examination.—Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology, Materia Medica, and Practical Pharmacy. Fourth Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, Therapeutics, and Special Pathology. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital one month, and lunatic asylum three months. Vaccination instruction must be taken out and courses of Ophthalmology, Medical and Surgical Anatomy, and Operative Surgery.

*Degrees of Doctor of Medicine and Master of Surgery.*—At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both.

Candidates for either of these degrees have to present a thesis embodying observations in some subject embraced in one of the departments of the medical curriculum, and in addition pass a general examination in Principles and Practice of Medicine for the M.D., and general examination in Principles and Practice of Surgery, including operations on the cadaver for the M.Ch. It will be in the power of the Board of Examiners to exempt from the practical parts of the examination a candidate whose thesis is of exceptional merit from any part of these examinations.

*Degree of Ph.D.*—The Degree of Doctor of Philosophy in the Faculty of Medicine is conferred under the following regulations:—(1) Candidates must possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University. (2) Candidates must have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University, provided that after the first year of the course candidates may be permitted to devote such periods as may be deemed desirable by the University to research elsewhere, under approved conditions. (3) On completing the course of

advanced study and research candidates are required (a) to present a thesis on the subject of their advanced study and research, and to satisfy the examiners that it contains original work worthy of publication; (b) to submit themselves for an oral examination on the subject of the thesis and on the general field to which their subject belongs, and, if required, for a written examination and to satisfy the examiners in the examination as well as in the thesis presented. (4) The minimum fee payable by candidates to be 10 guineas for each academic year, exclusive of laboratory fees. As in the case of other doctorates, a fee of £10 to be payable for the examination.

*Fees.*—Matriculation, £2; First Examination, £2; Second Examination, £2; Third Examination, £2; Fourth Examination, £2; Final Examination, £8; M.D. or Ch.M., £10.

At the University of Birmingham the following Scholarships are awarded:—(a) Myers Travelling Studentship of £150, tenable for one year, awarded by vote of committee to M.B., Ch.B. Birm., B.Sc. candidates, tenable at some University or Hospital not in Great Britain or Ireland; (b) Ingleby Scholarship of £10, awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (c) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (d) Sands Cox Scholarship of £42, tenable for three years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the July Matriculation; (e) Dental Scholarship of £37 10s., Open Competitive Examination in subjects learned during apprenticeship; (f), (g), (h), and (i) Four Queen's Scholarships of £10 10s. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of *Materia Medica* and *Practical Pharmacy*. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (j) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (k) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases.

*Clinical Instruction.*—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital, details of which follow.

The clinical instruction of the Birmingham medical students is carried on under the direction of the University Clinical Board. The hospitals present an excellent field for clinical work, possessing more than 500 beds, treating annually over 8000 in-patients and 100,000 out-patients. The students spend part of their curriculum in each hospital, and thus have every opportunity of acquiring a varied, full, and practical knowledge of their professional work. The curriculum is adapted in the first place to meet the needs of the students of the University of Birmingham, but it is also well adapted to the requirements of students preparing for the examinations of all other universities and licensing bodies. At the General Hospital there are open to the students the following appointments: A surgical registrar, £200 per annum; a resident medical officer, elected annually (£155); a resident surgical officer, elected annually and eligible for re-election for three years (£180); a resident pathologist, elected for six months (£100); three surgical casualty officers, elected annually and eligible for re-election (£50); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £100 a year; two house surgeons to the gynaecological, ophthalmic, and aural departments are elected every six months, receiving board, residence, and a salary of £100 a year; two assistant house surgeons are elected every three months, receiving board,

residence, and salaries at the rate of £40 a year; a resident medical officer at the Jaffray Hospital, who is elected annually but is eligible for re-election, and who receives £150 a year; and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £90 a year. Thirty-eight other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Lunatic Asylums, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopaedic and Spinal Hospital, at the Maternity Hospital, and at the Ear and Throat Hospital.

*Post-graduate Courses.*—A "Lectureship in Psychotherapy" has recently been established in the University, the first annual lecturer being Dr. Bernard Hart, of University College Hospital, who gave a course of ten lectures during the Summer Session for practitioners and students of the University Medical School. The Lecturer for 1920 has not yet been appointed.

A course of six lectures (with clinical demonstrations) on "Venereal Diseases" was also held during the Summer Session for practitioners and students, the lecturer being Dr. A. Douglas Heath, Physician to Skin Department of the Birmingham General Hospital. It is proposed to provide a further course of instruction in this subject during the ensuing session.

THE BIRMINGHAM GENERAL HOSPITAL.—360 beds are in daily use, 5620 in-patients per annum. Special wards for children, gynaecological, septic and infectious cases; special beds for eye, ear, and skin cases. About 50,000 out-patients per annum. Laboratories for bacteriology and morbid histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on the most modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments. The Jaffray Branch Hospital contains 54 beds.

THE QUEEN'S HOSPITAL.—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynaecology and ophthalmology.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of over 250. This institution is recognised by Universities and the Royal College of Surgeons, England, and Royal College of Physicians, London, as an ophthalmic hospital at which clinical instruction in ophthalmology may be received. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations.

#### UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Hygiene (M.H.).

*Degrees of Bachelor of Medicine and Bachelor of Surgery.*—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 21 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are:

(1) Chemistry, Inorganic, Organic, and Physical; (2) Biology (Zoology and Botany); and (3) Physics. The examination is divided into two parts—namely, (1) Chemistry and Physics, and (2) Biology; and candidates may present themselves in these parts separately. The subjects of the Second Examination are (a) Anatomy and Physiology (including Physiological Chemistry and Histology), and (b) *Materia Medica*, Pharmacy, and Pharmacology. Candidates may present themselves in (a) or (b) separately. The subjects for the Final Examination are: (1) General Pathology, Morbid Anatomy, and Bacteriology; (2) Forensic Medicine, Toxicology, and Public Health; (3) Obstetrics and Diseases of Women; (4) Surgery, Systematic, Clinical, Operative, and Practical, including Ophthalmology; (5) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children, and Therapeutics. The Final Examination is divided into three parts, the first consisting of subject (1), the second of subject (2), the third of subjects (3), (4), and (5). Candidates may present themselves in these parts separately. Candidates for the third part must have completed the fifth year of medical study.

*Degrees of Doctor of Medicine and Master of Surgery.*—No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since he passed the examinations for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine: provided always that original work published in scientific journals or separately shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree.

At this University the following Scholarships and Fellowships and Prizes are awarded:—(a) and (b) Robert Gee Entrance Scholarships, two annually, of £25 each, tenable for two years, Joint Matriculation Board Examination held in July, open to First M.B. Course Students; (c) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects, Perpetual Course at the University; (d) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination among Senior Students in Anatomy, Physiology, Pharmacology, and *Materia Medica*; (e) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects, and Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students; (f) University Scholarship of £25 for one year, awarded on results of Second Examination for the degrees; (g) Holt Fellowships, Physiology and Pathology, of £100 each, for one year; (h) Gee Fellowship, Anatomy, of £100, for one year; (i) Alexander Fellowship, Bacteriology and Pathology, of £100, for one year; (j) Johnston Colonial Fellowship, Bio-Chemistry, of £100, for one year; (k) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (l) Thelwall Thomas Fellowship, Surgical Pathology, of £100, for one year; (m) Ethel Boyce Fellowship in Gynaecological Pathology, of £100, for one year; numerous prizes and medals; (n) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; students who are or have been registered day students of the University are eligible for election; holder to proceed to a University degree in Medicine; candidates must apply in writing to the Registrar, forwarding evidence of their qualifications, on or before July 1st.

*Medical School Buildings.*—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine, Bio-Chemistry, and Tropical Medicine; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology.

*Clinical Instruction.*—The Clinical School of the University now consists of four general hospitals—the Royal Infirmary,

the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1134 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

*School of Veterinary Science.*—There is a school of Veterinary Science in connexion with the University which provides full courses of instruction for the M.R.C.V.S. Degrees of B.V.Sc., M.V.Sc., and D.V.Sc., together with a diploma in Veterinary Hygiene, are also granted by the University.

*Public Health Department.*—This is located in a separate building known as Ashton Hall, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

#### THE VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine is awarded by examination to registered medical practitioners.

*Degrees of Bachelor of Medicine and Bachelor of Surgery.*—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the first M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations. (These are now under revision.)

*The First Examination.*—(1) Inorganic Chemistry and Physics; (2) Biology; and (3) Elementary Organic Chemistry and Bio-Chemistry. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into three parts: Part 1, Inorganic Chemistry and Physics; Part 2, Biology; Part 3, Elementary Organic Chemistry and Bio-Chemistry; and the candidates may pass in these parts separately under certain conditions.

*The Second Examination.*—(1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology. Candidates may pass in (1) and (2) separately under certain conditions.

*The Third Examination.*—(1) Pathology; (2) Pharmacology and Therapeutics; (3) Hygiene. These subjects may be taken separately under certain conditions.

*The Final Examination.*—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynaecology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination). These subjects may be taken separately under certain conditions.

Candidates for the Final Examination must have completed the fifth year of medical study.

*Degree of Doctor of Medicine.*—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dis-

sertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be partly written, partly practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

*Degree of Master of Surgery.*—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; and (6) Pathology and Bacteriology.

Communications should be addressed to the Registrar, The University, Manchester.

*Scholarships, Fellowships, and Prizes.*—At this University there are 22 Foundation Scholarships, 12 Exhibitions, five being for subjects connected with medical study, a Surgical Prize, a University Fellowship (Leech Fellowship, £100), Research Fellowships in Public Health, and Honorary Research Fellowships. 13 Entrance Scholarships are tenable for Medical courses; one Scholarship is offered in Surgery, Biology, Physiology, and Diseases of Children respectively, and one General Medical and Surgical. Exhibitions are offered in Physiology and Anatomy, and one for French and German. "The Dumville" Surgical Prize is awarded on the results of the Final Examination in Surgery in the Summer Term, £15. The Leech Fellowship (£100) is for the encouragement of study and research, and is open to persons who have graduated M.B., Ch.B., in the University not more than 18 months previously. The Honorary Research Fellowships, tenable for two years, conferring the right of free use of the laboratories, are awarded generally in October on application, with evidence of capacity for independent investigation.

There are many entrance scholarships, the examinations for which are held in the month of May. Full particulars can be obtained from the Dean.

*The Medical School.*—This medical school, largely extended in 1895, is provided with dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

*Clinical Studies.*—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, which together with the associated hospitals at Cheadle contains 1109 beds, exclusive of those reserved for military cases, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

*Clinical Instruction.*—THE MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 884 (including 472 temporary military beds). The remaining beds are allocated to civilians. The medical side consists of five units, each unit having a testing room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing, and apparatus rooms, and its own class-room attached.

Of these units all are occupied. The fine educational block provides very handsomely for the wants and comforts of the students, there being separate suites of rooms for the men and the women, and also a large common reading room, a lecture theatre, and a museum. The present annual average number of in-patients is 12,500, of out- and home-patients 25,000, and the list of casualties in the accident room has averaged 17,000 per annum. About 8200 operations are performed annually in the operation theatres. Associated with the infirmary are: (1) the Convalescent Hospital at Cheadle, containing 136 beds; (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the city for casualty and out-patient work, and 62 temporary military beds. The Associated Hospitals thus contain 1450 beds and are under the same management. Women students are admitted to the practice of the Infirmary on the same terms as men.

*Fees.*—Medical Practice: Three months, 5 guineas; six months, 8 guineas; 12 months, 12 guineas; full period required by the Examining Boards, 42 guineas.

Two Entrance Scholarships in Medicine of the value of £100 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are in the College Syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

The secretary to the Infirmary is Mr. F. G. Hazell.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and St. Anne's-on-the-Sea.—The hospital contains 188 beds and 24 in the Convalescent Home, St. Anne's-on-the-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the new Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

THE MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 70 beds. Out-patients are seen daily from 8.30 to 10 A.M.

#### UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

*Degrees of Bachelor of Medicine and Bachelor of Surgery.*—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University subsequently to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

*The First Examination.*—The First Examination consists of: Part I., Physics and Chemistry; Part II., Biology. Candidates will be allowed to pass the two parts separately.

*The Second Examination.*—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

*The Final Examination.*—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Diseases and Diseases of Children; Surgery—Systematic, Clinical, and Practical; Obstetrics, and Gynaecology—Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

*Degree of Doctor of Medicine.*—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, to pass an examination.

The first term commences on Oct. 1st. Prospectus, &c., can be obtained from the Dean of the Medical School.

*Clinical Instruction.*—THE LEEDS GENERAL INFIRMARY, in connexion with this medical faculty, has accommodation for 620 in-patients, including 88 beds at branch hospitals in the country. During the last year 9910 in-patients and 34,143 new out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification.

#### UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The courses and degrees in the Faculty of Medicine are open to men and women alike.

Candidates for a medical degree shall have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board.

A candidate for the degrees of M.B., Ch.B. shall produce certificates that he will have attained the age of 21 years on the day of graduation; that he has pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

*Degrees of Bachelor of Medicine and Bachelor of Surgery.*

*The First Examination.*—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

*The Second Examination.*—The subjects of the examination are Anatomy and Physiology.

*The Third Examination.*—The subjects of the examination are Pathology and Pharmacology. A candidate entering for the first, second, or third examination, who shall pass creditably in one subject of either examination and obtain a certain minimum of marks in the other, may enter for such other subject separately in a subsequent examination. Candidates must have completed the fourth year of professional study.

*The Final Examination.*—The subjects of the examination are Medicine (including Forensic Medicine, Public Health, Mental Diseases, and Diseases of Children); Surgery; and Obstetrics (including Gynæcology). Candidates must satisfy the examiners in all subjects at the same examination. Candidates must have completed the fifth year of professional study.

*Degree of Doctor of Medicine.*—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

*Degree of Master of Surgery.*—Candidates for the degree of Ch.M. must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital

or other public institution, affording full opportunity for the study of Practical Surgery.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology.

*Scholarships, &c.*—At this University, in addition to four Edgar Allen scholarships of £100 a year for three years, holders of which can take the courses in the Faculty of Medicine, there are 8 scholarships and a Town Trust Fellowship. Full particulars as to curriculum, scholarships, &c., may be had on application to the Registrar or to the Dean of the Medical Faculty.

*The Medical School.*—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of a Students' Representative Council, elected annually. There are large and comfortable common rooms both for men and women students. A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c., at extremely moderate prices. The University journal, *Floreamus*, edited by a committee of staff and students, is published each term. The University Hostel, "Oakholme," Clarkehouse-road, is recognised by the Senate as a residence for women students, full particulars of which may be obtained of the tutor for women students.

*Clinical Instruction.*—The University is within easy reach of the various hospitals with which it is connected for clinical purposes. These are as follows: The Royal Infirmary (Secretary, Mr. J. W. Barnes), containing 320 beds, with an annual average number of over 3800 in-patients, over 11,500 out-patients, and over 23,000 casualties; the Royal Hospital (Hon. Sec., *pro tem.*, to the medical and surgical staff, Mr. Vincent Townrow), with 191 beds, and an annual number of 3000 in-patients, over 20,000 out-patients, and nearly 20,000 casualties; and the Jessop Hospital for Diseases of Women, with 80 beds, about 750 in-patients, and over 3000 out-patients; also a Maternity department, with about 450 in-patients per annum and about 700 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (570 beds) and on Mental Diseases at the South Yorkshire Asylum (1610 beds). For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 511 beds for the treatment of medical, surgical, and special cases. There are special departments for the treatment of Diseases of the Eye at each institution, with wards assigned to them. In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. During the last year over 6000 patients passed through the wards of the two institutions, while those attending as out-patients numbered over 45,000. The department of Pathology and Bacteriology in the University is fitted with every requirement for the most advanced work in these subjects.

*Fees.*—The Composition Fee is £30 a year for each of the five years and entitles the student to attendance on all the Lectures, Laboratory Classes, and Hospital practice required for a Medical and Surgical Degree in the University or for the ordinary qualifying examinations of the various Examining Boards. The composition fees do not cover the cost of apparatus, instruments, parts for dissection in anatomy, &c., all of which must be provided by the student when and as required. The fees are payable in instalments extending over the five years of the curriculum.

#### UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the Matriculation Examination, or to pass such examination as

may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike. The winter session commences on Oct. 1st, 1919.

*Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.*—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five and a half years, of which three shall have been passed in the University, and two of these three subsequent to pass in the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations.

*The First Examination.*—The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

*The Second Examination.*—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). Parts I. and II. may be passed separately or together.

*The Final Examination.*—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). Candidates may pass I. and II. together, or separately, and Forensic Medicine and Toxicology may, at the option of the candidate, be taken either with Part I. or Part II.

*Degree of Doctor of Medicine.*—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

*Degree of Master of Surgery.*—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery.

*Clinical Instruction.*—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat, and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well-equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

#### UNIVERSITY OF WALES.

This University has the privilege of granting degrees in Medicine and Diplomas in Public Health. At the three constituent Colleges of Aberystwyth, Bangor, and Cardiff there are Professors of Chemistry, Botany, Zoology, and

Physics, so that the students of the University can obtain proper instruction in the ancillary subjects. The foundation of a Medical Faculty has been laid at University College, Cardiff, where there is a recognised school of medicine.

*University College, Cardiff: School of Medicine.*—All classes are open to both men and women students who may spend three or four out of their five years of medical study at Cardiff. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal Colleges, and other licensing bodies of Great Britain and Ireland, and they are specially adapted to meet the needs of those University students studying for Cambridge and London degrees. Students who are preparing for these examinations may compound for their courses by paying a fee of £63, while a composition fee of £41 10s. includes all the necessary courses for the first and second examinations for the Diploma of the Conjoint Board. In all cases the composition fees may be paid by instalments. Hospital instruction is given at the King Edward VII.'s Hospital, Cardiff. The attention of students about to matriculate is drawn to the numerous entrance scholarships offered for competition at University College, Cardiff, in April next, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. In the department of Public Health established in 1899 instruction is given qualifying for the D.P.H. examinations. Further information may be obtained from the Dean of the Faculty of Medicine.

*Clinical Instruction.*—KING EDWARD VII.'S HOSPITAL, CARDIFF.—Students can attend the practice of this Hospital, which contains 320 beds, 104 beds for military patients. Founded 1837. In-patients, 2830; out-patients, 16,303.—SWANSEA GENERAL AND EYE HOSPITAL.—Hospital, 238 beds, 183 civilian, 100 (sailor and soldier pensioners); Convalescent Home, 27 beds. In-patients, 2516; out-patients, 7953.

#### ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

##### EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Any candidate who desires to obtain both the Licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth. Six months of the curriculum may be spent in an Institution recognised by the Board for instruction in Chemistry, Physics, Practical Chemistry, and Biology.

*Professional Examinations.*—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and September or October unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, O.B.E., secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, W.C., 14 clear days before the day on which the examination

commences, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, Elementary Biology, and Practical Pharmacy. A candidate may take this examination in three parts at different times (Chemistry and Physics must be taken together until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, in Practical Pharmacy, and Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution, but he may take Pharmacy at any time during the curriculum. A candidate rejected in one part or more of the *First Examination* will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

*Note.*—Candidates who have not passed Parts I., II., and III. by May 1st, 1920, will be examined in *Materia Medica* and *Pharmacology* as part of the *Second Examination* instead of *Practical Pharmacy*. The new regulations and the synopsis of the examination will be issued shortly.

The fees for admission to the *First Examination* are as follows: For the whole examination, £10 10s.; for re-examination after rejection in Parts I. and II., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the *Second Examination* are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the *Second Examination* on production of the required certificates of professional study. The study of Anatomy and Physiology before passing in two of the first three parts of the *First Professional Examination* is not recognised.

A candidate referred on the *Second Examination* will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the *Second Examination* are: £10 10s. for the whole examination and £6 6s. for re-examination after rejection.

The subjects of the *Third or Final Examination* are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the *First Examination* will not be re-examined in that subject at the *Third Examination*. Part II. Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III. Midwifery and Diseases Peculiar to Women. Candidates may present themselves for Parts I., II., and III. of the examination separately or together at the expiration of not less than two years (24 months) from the date of passing the *Second Examination* on production of the certificates of study required for the respective parts, provided that the examination is not completed before the expiration of five years from the date of passing the Preliminary Examination.

The fees for admission to the *Third or Final Examination* are as follows: For the whole examination, £21. Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5s.; for re-examination in Practical Pharmacy (if taken at this examination), £2 2s. Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances, £5 5s. Part III. For re-examination in Midwifery and Diseases Peculiar to Women, £3 3s.

A candidate referred on the *Third or Final Examination* will not be admitted to re-examination until after

the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the *First* and *Second Examinations* of the Examining Board, may enter for the *Final Examination* at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the *First* and *Second Examinations* of the Examining Board may present themselves for the *Final Examination* under special conditions which can be ascertained on application to the Secretary.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the English Conjoint Board, the Royal College of Physicians of London and the Royal College of Surgeons of England grant honour diplomas, which no longer give the right to practise professionally if held separately. The Royal College of Physicians of London has two such diplomas, the *Fellowship* which is a purely honorary distinction and the *Membership* which is obtained by examination.

*Membership.*—Every candidate for the Membership of the College must furnish proof of having attained the age of 25 years. Candidates must not be engaged in trade, dispense medicine, make any arrangement with a chemist or any other person for the supply of medicine, or practise medicine or surgery in partnership, by deed or otherwise. Any candidate being already registered or having passed a qualifying examination in accordance with the Medical Act of 1886, who has obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British colony, or who has obtained a foreign qualification entitling him or her to practise medicine or surgery in the country where such qualification has been conferred, wherein the courses of study and the examinations to be undergone previously to graduation have been adjudged by the Censors' Board to be satisfactory, will (if the Censors think fit) be admitted to the Pass Examination. The nature and extent of this examination will, in the case of each candidate, be determined by the Censors' Board. All other candidates must produce proof of having passed the examinations required for the Licence of the College. The examination is directed partly to pathology and partly to the practice of medicine and may be modified in circumstances to be ascertained by application to the Registrar. For example, candidates under 40 years of age are examined in an ancient and a modern language, a test from which their seniors are exempt. The fee for admission as a Member of the College is 40 guineas, except when the candidate for Membership is a Licentiate of the College, in which case the fee already paid for the Licence shall be deducted from the 40 guineas. The fee for the examination is £6 6s.

*Fellowship.*—The Fellows are selected annually from the ranks of the Members by the Comitia of the College.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellowship on a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

*Fellowship.*—The examination for the Fellowship is divided into two parts—viz., the *First Examination* and

the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and the questions on these subjects may require an elementary acquaintance with Comparative Anatomy and Physiology. The examination is partly written and partly *vivâ voce*. The subjects of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examination is partly written and partly *vivâ voce* and includes the examination of patients and the performance of operations on the dead body. The examinations are held during the months of May and November of each year.

The fees for examination are:—First Examination, each admission, 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 17 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a member of the College is admissible to the first Professional Examination for the Fellowship on the production of evidence of having passed the First and Second Examinations of the Examining Board in England by the Royal College of Physicians of London and the Royal College of Surgeons of England (or, if a member of a University recognised by the College for the purpose, of having passed the Examinations in his University equivalent to the First and Second Examinations of the Board) and on the production of certificates of attendance upon certain courses of study described in the Regulations.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

#### SOCIETY OF APOTHECARIES OF LONDON.

There are two examinations—Primary and Final. The Final examination is divided into Section I. and Section II. The Primary examination is held quarterly. Final examinations are held monthly. No examinations are held in the month of September.

The Primary examination consists of two parts. Part I. Elementary Biology; Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. A schedule for the Primary examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. Section I. of the Final examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. includes the Principles and Practice of Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynaecology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Section I. of the Final examination cannot be passed before the expiration of 45 months from the date of commencement of

medical study, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Society. Section II. of the Final examination consists of two Parts. Part I. Clinical Surgery; Part II. Clinical Medicine and Medical Anatomy. Section II. cannot be passed before the end of the fifth year.

The course of study for the *Primary examination* is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with Demonstrations, 12 months; Physiology, six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School recognised by the Society. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination, or in a public hospital, infirmary, or dispensary.

The course of study for the *Final examination, Section I.*, includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of two winter and two summer sessions; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership, six months; Performance of Surgical Operations on the Dead Body; lectures on Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship, six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynaecology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on 20 Midwifery cases. The course of medical study must extend over the above-mentioned period of 45 months, and the offices of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Two years must elapse after a candidate has passed the examination in Anatomy and Physiology before he is eligible to sit for any part of the Final examination.

The course of study for the *Final examination, Section II.*, includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of 12 months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. No candidate is eligible for the Final examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be obtained of the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to Section II. of the Final examination the candidate must produce certificates: (1) of being 21 years of age; (2) of moral character; (3) of the course of medical study; (4) of proficiency in vaccination signed by a teacher authorised by the Local Government Board; and (5) of instruction in the administration of anaesthetics. Candidates intending to present themselves for examination are required to give 14 days' notice. A form for this purpose will be sent on application.

Licentiates are eligible for the Membership of the Society of Apothecaries. Particulars may be obtained on application to the clerk.

The fee for the Licence is 20 guineas. Female candidates are admitted to examinations. The examination offices are open from 10 A.M. to 4 P.M.: on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

### METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

**THE SEAMEN'S HOSPITAL SOCIETY** possesses two hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds; and the Angus Home 30 beds. It has also two Dispensaries—one in the East India Dock-road and the other at Gravesend—from which the patients are transferred to the hospitals. Secretary: Mr. P. J. Michelli, C.M.G.

**WEST LONDON HOSPITAL**, Hammersmith, W.—This hospital has 160 beds, all of which are constantly in use. 2440 in-patients and 30,322 out-patients, whose attendances numbered 155,870, were treated last year. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards every morning and afternoon. Lectures and demonstrations are in abeyance during the war. Special Classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynaecology, Medical Electricity, Operative Surgery, Bacteriology, Anaesthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Tropical Medicine, Cystoscopy, Venereal Diseases, and Operative Ophthalmology. The accommodation for post-graduates consists of a large lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology, a class being held every month. The fees for hospital practice, including lectures, are £6 6s. for three months, or £15 15s. for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Dr. Arthur Saunders, or Vice-Dean, Mr. Bishop Harman, at the hospital. Secretary of the Hospital: Mr. A. Betteridge.

**GREAT NORTHERN CENTRAL HOSPITAL**, Holloway-road, N.—This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the Honorary Staff there are six Anaesthetists, Pathologist, Resident Medical Officer, one resident House Physician, three resident House Surgeons, and resident casualty officer. The hospital contains 430 beds (including emergency beds), which are fully occupied. There is also a ward for children under five years of age. The large rectangular and circular wards, each of which contains 35 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. There is also a well-appointed electro-therapeutic department. The Pathological Department has been extended and is under the control of a Director of Clinical Pathology. The Reckitt Convalescent Home at Clacton-on-Sea belongs to the hospital. It contains 60 beds. Special departments have also been established for the treatment of tuberculosis and venereal diseases. A Hospital of Recovery has now been established at "Summerlee," East Finchley, which is placed at the disposal of discharged soldiers and sailors as well as civilians. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. Further particulars from the Secretary of the Medical Committee at the Hospital.

**PRINCE OF WALES'S GENERAL HOSPITAL**, Tottenham, N.—This general hospital is in the midst of a densely populated neighbourhood of more than half a million inhabitants. It contains medical, surgical, gynaecological, and children's

wards, having 125 beds. There are special departments for gynaecological cases, diseases of the eye, ear, throat, and nose, skin diseases, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 p.m. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are four Resident Medical Officers, and Clinical Assistants are appointed under certain conditions. Further particulars in regard to the hospital may be obtained from Mr. H. W. Carson, Secretary to the Medical Committee, 111, Harley-street, W.; or from Dr. A. J. Whiting, Dean of the North-East London Post-Graduate College, 19A, Cavendish-square, W. Secretary: Mr. F. W. Drewett.

**LONDON TEMPERANCE HOSPITAL**, Hampstead-road, N.W. (Established 1873; Incorporated 1917).—The hospital contains 120 beds. The in-patients in 1918 were 1154, and the out-patients and casualties numbered 15,803 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Mondays at 2 p.m., Tuesdays, Wednesdays, and Fridays at 9 a.m.

**HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL**.—The Hampstead General Hospital (Haverstock Hill) and the North-West London Hospital (formerly at Kentish Town) have been amalgamated since 1907. The Hampstead General Hospital (128 beds—viz., 102 free, 6 isolation, &c., and 20 paying or contributory) accommodates the in-patients from the districts hitherto served by both hospitals. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients Department, Bayham-street, Camden Town. Further particulars from the secretary at the hospital (Haverstock Hill, N.W. 3).

**ELIZABETH GARRETT ANDERSON HOSPITAL**, 144, Euston-road, N.W.—A considerable number of the students work in the E.G.A. Hospital under the visiting staff, and in return for much valued clinical teaching they perform the duties assigned to students in the wards of a general hospital. Secretary: Miss Imogen H. Murphy.

**THE SOUTH LONDON HOSPITAL FOR WOMEN**, South Side, Clapham Common, S.W.; Out-patient Department: 86-90, Newington Causeway, S.E.—This hospital, officered entirely by medical women, is a general hospital for women, girls, and small children of both sexes, and provides accommodation for 80 patients. All diseases are treated with the exception of acute infectious fevers and mental disease. There are Ophthalmic, X Ray, and Pathological Departments. The provision of additional facilities for post-graduate training for medical women is one of the special objects of the hospital. The number of in-patients treated during the year 1918 was 1173. At the Out-patient Department in Newington Causeway 7386 new cases were treated during the past year, the total number of out-patient attendances amounting to 31,416. Clinical assistants (qualified women only) are from time to time appointed in the Out-patient Department. Secretary: Miss M. E. Ridler.

**FRENCH HOSPITAL AND DISPENSARY**, Shaftesbury-avenue, W.C.—This hospital, which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language, has 74 beds. The Convalescent Home and Retreat for Aged French People at Brighton contains 61 beds. Secretary: Mr. G. Pondepeyre.

**ITALIAN HOSPITAL**, Queen-square, W.C.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 50 beds.

**GERMAN HOSPITAL**, Dalston, E. 8.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for cases of emergency and of accident. It has 142 beds, including a sanatorium with 10 beds. Also a convalescent home at Hitchin with 40 beds, occupied, since 1915, by convalescent British soldiers.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC** (Albany Memorial), Queen-square, Bloomsbury, W.C.—The hospital, with the Finchley branch, and branches in Bloomsbury, Maidenhead, and Clapham Park, contains 324 beds and cots. The physicians attend every Monday, Tuesday, Thursday, and Friday at 2 p.m. In- and out-patient practice at that hour. Clinical Clerks are appointed under the in-patient and out-patient physicians. Lectures are given on Tuesdays and Fridays at 3.30. The hospital has been recognised by the Conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, hospital practice, and fees should be addressed to the Secretary at the hospital.

**HOSPITAL FOR EPILEPSY AND PARALYSIS, &C., Maida Vale, W. (85 beds).**—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. Secretary and General Superintendent: Mr. H. W. Burleigh.

**WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.**—Graduates in medicine and senior students may attend demonstrations in the Out-patient Department. No fees are charged. The Savill Prize and Medal are at present in abeyance, as well as routine demonstrations by the staff.

**BETHLEM ROYAL HOSPITAL, St. George's-road, S.E.**—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They are permitted to reside in the hospital for a term generally not exceeding six months, commencing May 1st and Nov. 1st, and are provided with apartments, complete board, attendance, laundry, and a salary at the rate of £100 per annum. They are under the direction of the Physician Superintendent and are elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital and qualified practitioners and other students may attend for a period of three months on payment of a fee.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.**—The hospital contains 333 beds. The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six House Physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. Pupils are admitted to the practice of the hospital: terms, £1 1s. for one month; three months, £22 2s.; perpetual, £55s. Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical Assistants are appointed to the Assistant Physicians in the out-patient department and Clinical Clerks to the Physicians in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. Dean of the Medical School: Dr. L. S. Burrell. Lectures are given on Wednesday afternoons during the terms. Free to students and post-graduates.

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.**—During the past year 1083 in-patients have been treated in the wards. The out-patients treated during 1918 numbered 10,596. Address "Secretary of the Medical Committee."

**ROYAL CHEST HOSPITAL** (for all affections of the heart and lungs), City-road, E.C. (80 beds.)—This hospital provides accommodation for 80 in-patients. Expenditure for 1918 £14 409 income £16,375. The attendance of out-patients averages 25,000 annually. Secretary: Mr. A. T. Mays.

**THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, NORTHWOOD, CENTRAL OUT-PATIENT DEPARTMENT, Fitzroy-square, W.**—The hospital contains 110 beds. Number of in-patients, 437; out-patients, 3546. Resident Medical Staff. Clinical Demonstrations are given by the Visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards and in the out-patient department. Secretary: Mr. W. J. Morton. Offices: 7, Fitzroy-square, W.

**QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.**—This hospital receives about 1800 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. A Residential College provides accommodation for five men at a time, students and qualified practitioners and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council. Women students are received. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

**THE HOSPITAL FOR WOMEN, Soho-square, W.**—In connexion with the out-patient department there has been for some years a well-organised Clinical Department. The appointments are open to qualified medical men and women. Every facility is afforded them by the gynaecologists in the out-patient department of obtaining experience in diagnosis and treatment and the practical use of instruments. Fee for one month £22 2s.; for each subsequent month the same. The hospital contains 67 beds. In the out-patient department there were over 4000 new cases during the past year, the total number of out-patient attendances being 14,500. This large number affords exceptional opportunities for examining and studying most of the varieties of the diseases of women. Applications should be made to the Secretary, Mr. Alfred Hayward.

**SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.**—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. Demonstrations are given daily in both departments. The fees, payable in advance, are £3 3s. for three months. Full particulars may be obtained on application to the Secretary at the hospital. There are 70 beds. Secretary: Mr. G. H. Hawkins.

**EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.**—The hospital maintains 130 cots, and on an average 245 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to Mr. W. M. Wilcox, the Secretary, at the hospital.

**THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. 1,** contains 210 beds, besides 30 beds at the Branch Hospital, Highgate. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to six medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Fees for hospital practice, one month, £2 2s.; three months, 5 guineas; perpetual ticket, 10 guineas. Clinical Clerks, 1 guinea for one month. Ophthalmological Clerkships.—Clinical Clerks are

appointed once a month. Fees £1 1s. for one month's attendance. Pathological Clerkships.—Facilities are afforded for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology in the Pathological Laboratories. Clerks attend for about four hours daily. Fees: For one month, £3 3s.; for two months, £5 5s.; for three months, £6 6s. A reduction is made in the case of those already holding tickets for general attendance at the hospital. Time so spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, and by the Conjoint Board for England as part of the approved curriculum for students entering for a final examination. These appointments are open to students of all recognised medical schools. In addition, special courses in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily. Details may be obtained by application to the dean or secretary at the hospital. The medical school is a constituent part of the new London Post-Graduate Association. Secretary: Mr. Stewart Darmady.

**EVELINA HOSPITAL FOR SICK CHILDREN**, Southwark Bridge-road, S.E.—This hospital contains 76 cots and a very extensive Out-patient Department. About ten clinical assistants (either sex), to work with the Honorary Medical Staff for Out-patients, are appointed quarterly for a period of three months; there is no salary attached to these posts; but, on the other hand, no fees are charged. Secretary: H. C. Staniland Smith.

**VICTORIA HOSPITAL FOR CHILDREN**, Tite-street, Chelsea, S.W.—The hospital contains 104 beds and has a large out-patient department (over 1200 weekly); the home at Broadstairs has 50 beds. Out-patients are seen as under:—Diseases of the Eye: Tuesday, 2 P.M. Diseases of the Skin: Wednesday, 1.30 P.M. Whooping-cough Cases: Friday, 2.30 P.M. Dental Cases: Thursday, 1.30 P.M. Medical and Surgical Cases: Mornings at 9.30. Accidents and urgent cases are admitted at any time. Post-graduate courses of lectures are being arranged for the winter. Secretary, Mr. H. G. Evered.

**THE QUEEN'S HOSPITAL FOR CHILDREN** (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E.2 (Telephone 305 Dalston.) For the sick children of the poor under 14 years of age. Established 1867. 134 beds in London and 36 at the seaside branch. "Little Folks" Home, Bexhill.—During the past year 1481 in-patients and 53,119 out-patients (attendance 107 075) were received. The surgeons attend on Tuesdays and Wednesdays at 1.45 P.M. and Fridays and Saturdays at 9.30 A.M.; the physicians daily at 1.45 P.M., except Saturday, 9.30 A.M., and Wednesday and Friday, 9.30 A.M., as well as 1.45 P.M. The practice of the hospital is open to students by arrangement with the medical staff. Applications should be made to the Secretary, Mr. T. Glenton-Kerr.

**THE BELGRAVE HOSPITAL FOR CHILDREN**, Clapham-road, S.W.—Clinical Assistants (men or women) are from time to time appointed to the members of the Visiting Staff attending in the Out-patient Department at this hospital, and facilities are given for attendance in the wards.

**ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE**, Queen-square, W.C.—At this hospital students who have obtained a recommendation from their teachers can attend to see the practice. The out- and in-patients' clinic is held on Mondays and Thursdays at 3 P.M.

**ROYAL LONDON OPHTHALMIC HOSPITAL** (Moorfields, 1804-1899), City-road, E.C. 138 beds.—This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. In 1918 there were 2339 in-patients, the out-patients were 41,725, of whom 36,101 were new out-patients, and the attendances were 98,186. Operations are performed daily from 10 A.M. to 1 P.M., and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3s.; perpetual, £5 5s. Special courses of instruction, which extend over a period of five months are given by members of the Surgical Staff; beginning in October and March. A composition fee of 24 guineas (£25 4s.) will entitle students to a perpetual ticket, and will admit them once to all the lectures and classes and to the examination for the hospital's full certificate. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants.

Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary Superintendent.

**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL**, King William-street, West Strand.—The hospital contains 40 beds. Out-patients, who number over 15,000 annually, are seen at 1 P.M., and operations are performed daily at about 3 P.M. The practice of the hospital is open to practitioners and students, men and women. Fees for six months, £3 3s.; perpetual, £5 5s.; shorter periods by arrangement. Students of the hospital are eligible for the posts of house surgeon, assistant house surgeon, pathologist, and clinical assistants. Secretary: Mr. John Hy. Johnson.

**ROYAL EYE HOSPITAL**, St. George's-circus, Southwark, S.E.—There are 40 beds and 2 cots. There were 56,513 attendances in the Out-patient Department last year, and the new patients numbered 21,848. Out-patients are seen daily 1.30 to 2.30 P.M. Dean: Mr. A. D. Griffith.

**CENTRAL LONDON OPHTHALMIC HOSPITAL**, Judd-street, St. Pancras, W.C.—This Hospital has 40 beds and possesses facilities for clinical teaching daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on refraction and other subjects are given during the winter months, commencing in October. The out-patient work begins at 1 o'clock, and operations are performed daily between 1 and 4 o'clock. Secretary: Mr. H. R. S. Druce.

**WESTERN OPHTHALMIC HOSPITAL**, Marylebone-road, N.W.—16 beds. Out-patient attendances 20 000. Both In-patient and Out-patient Departments of this Hospital are open to medical graduates. Fees £1 1s. per three months.

**HOSPITAL FOR DISEASES OF THE THROAT**, Golden-square, W. (with which is amalgamated The London Throat Hospital, Great Portland-street).—Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 P.M., and on Tuesdays and Fridays from 6.30 to 9 P.M. The hospital contains 60 beds for in-patients. There is an annual out-patient attendance of over 60 000. Minor operations are performed daily (except Monday) at 9.30 A.M. Major operations are performed on Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays at 10 A.M. Also Fridays at 2 P.M. Practitioners and medical students are admitted to the practice of the hospital at a fee of £5 5s. for three months, £7 7s. for six months, or £10 10s. for perpetual studentship. From amongst the students junior clinical assistants are appointed periodically. For terms and further information apply to the Dean, Mr. Geo. W. Dawson.

**CENTRAL LONDON THROAT AND EAR HOSPITAL**, Gray's Inn-road.—Clinical lectures: The hospital is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinique. Medical practitioners are invited to visit the wards, and are welcomed both in the operating theatre, when they are desirous of viewing the major operations, and in the out-patient operating room when minor operations are being performed. Clinical lectures are delivered from time to time, particulars of which are given in the medical journals, and at the hospital. Systematic classes and courses of instruction and demonstrations. Three courses of instruction are open to practitioners attending the hospital: First, the course in methods of examination and diagnosis; second, the course of systematic instruction in the diseases of the nose, throat, and ear; and third, the operative surgery class. The course in methods of examination and diagnosis is introductory in character. It comprises lessons of practical teaching in the actual examination of patients and in the manipulation of instruments. Systematic instruction in Diseases is more advanced. It consists of over 30 lessons in all on pathology, diagnosis, and treatment. Minute details in operative surgery are not gone into, as this is left to the operative surgery class. Full syllabus will be sent on application to the Secretary.

**THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL**.—The hospital is in Fitzroy-square, W. The Out-patient Department is opened daily at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays,

Thursdays, and Fridays at 10 A.M. Fee for one month's attendance at the hospital £1 1s., and for three months £2 2s. Clinical Assistants are appointed as vacancies occur, and have responsible duties.

**ROYAL EAR HOSPITAL**, Dean-street, Soho.—Steps are in progress for incorporating this hospital with University College Hospital as an Ear, Nose, and Throat Hospital department of the latter. At present the Hospital is closed.

**ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM**, City-road, E.C. (Founded 1835).—The hospital contains for men and women 56 beds. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. The number of out-patient attendances per year is 4258, and the average number of in-patients 705.

**ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES**, Henrietta-street, Covent Garden. Established 1860. New Hospital opened 1882.—The hospital contains 30 beds for men and 2 beds for women and children. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Mondays, Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 24; average out-patients seen daily, 100.

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN**, 49, Leicester-square, W.C. 2.—The in-patient department, 40 beds, is at 262, Uxbridge-road, W. 12. The out-patient practice is open to the medical profession every day at 2 and every evening (except Saturday) at 6. At the afternoon clinics demonstrations on the different diseases presenting themselves are given. Venereal Diseases, under the Government scheme, are admitted at all clinics. The X ray department is open every afternoon except Saturday. The Chesterfield Lectures are given on Thursdays at 6 P.M., October to March, commencing Oct. 10th. At the end of the course the Chesterfield medal may be competed for by those who have attended three-fourths of the lectures. Special laboratory courses in Pathology and Bacteriology of the Skin may be arranged for.

**LONDON LOCK HOSPITAL AND RESCUE HOME**.—In the Female Hospital at Harrow-road, W., there are 162 beds, and 633 patients were admitted in 1918. In the Male Hospital and Out-patient Department in Dean-street, Soho, W., there are 43 beds, which during 1918 accommodated 351 patients. 40,441 out-patients were treated. 10,000 injections of the substitutes for salvarsan were made in 1918. Male patients are seen at 91, Dean-street, on Mondays and Tuesdays from 1 to 2 P.M. and from 6 to 8 P.M.; on Wednesdays from 6 to 8 P.M.; on Thursdays at 11.30 A.M. and 5.30–7 P.M. (female patients); on Fridays from 5.30 P.M. (female patients); and on Saturdays from 2 to 4 P.M. (males). Pathological Department, Tuesdays at 6.30 P.M. Days for intravenous injections 91, Dean-street, W. 1. Tuesdays and Saturdays at 9 A.M. (men); women, Thursdays 11.30 A.M. and 5.30 P.M., Fridays at 5.30 P.M. Secretary: Henry J. Mason. Head office: 283, Harrow-road, W. 9.

#### ENGLISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

Under this heading we include all the hospitals which are recognised by the English Royal Colleges for a part of the required attendance on medical and surgical practice, for medical clerkships, and surgical dresserships. The list includes nearly every hospital of a general character in the country having more than 150 beds, though occasionally a large hospital is admitted because equally good opportunities are afforded to students at other institutions in its neighbourhood, while a small hospital may be included because no such facilities for study are present elsewhere. The list is arranged alphabetically as to the town where the hospital is located.

**BATH ROYAL UNITED HOSPITAL**, Bath.—This hospital contains 130 beds, and possesses a fine library. Secretary: Mr. J. M. Sheppard. V.D. Clinics are held on Tuesdays (for women), and on Fridays (for men) from 5 to 7 P.M.

**BEDFORD COUNTY HOSPITAL**, Bedford.—This hospital has 100 beds, with X Ray and Pathological Departments. Secretary: Mr. Beauchamp Wadmore.

**BRADFORD ROYAL INFIRMARY**, Bradford.—This hospital contains 215 beds. The material passing through the surgical wards consists of major operations, chiefly abdominal, and gynaecological work, and affords excellent facilities for either students or post-graduates. Plans for a new hospital of 382 beds have been adopted, and the building operations will be commenced as soon as the funds in hand will allow.

**THE ROYAL SUSSEX COUNTY HOSPITAL**, Brighton (220 beds).—This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Board of Management shall direct.

**KENT AND CANTERBURY GENERAL HOSPITAL**, Canterbury.—The hospital contains 110 beds. Pupils of the staff are admitted to the practice of the hospital and have the use of the library of the East Kent and Canterbury Medical Society for £7 7s. An X-ray apparatus has recently been given to the hospital. Operation day, Thursday, 11 A.M. Secretary: Mr. Arthur J. Lancaster.

**DERBYSHIRE ROYAL INFIRMARY**, Derby.—This hospital contains 320 beds. It was founded in 1810, and was entirely rebuilt and enlarged 1892–1915 on the most modern lines at a cost of over £144,000. There is a separate ophthalmic block of 33 beds, a separate children's block of 34 beds, and a special department for gynaecological cases. There are three resident house surgeons and a resident house physician. There are also well-equipped orthopaedic, X ray, electrical, and Finsen light departments. Registered medical students are admitted to witness the medical and surgical practice on payment of 10 guineas annually.

**ROYAL DEVON AND EXETER HOSPITAL**, Exeter.—The hospital contains 200 beds (including special children's ward) and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). The Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King. A department was opened in 1917 for the treatment of genito-urinary diseases; there are three sessions per week, two for men at 4 P.M. and 7 P.M., and one for women at 4 P.M.

**WEST OF ENGLAND EYE INFIRMARY**, Exeter.—Secretary: Mr. W. W. Beer. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1918, 2724.

**THE GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION**, Gloucester.—This hospital, which was granted the title of "Royal" on the occasion of King Edward VII.'s visit to Gloucester in the year 1909, has 140 beds. Secretary: Mr. H. P. Pike. In-patients, 1683; out-patients, 6739. An electrical and massage department has been established and venereal and neurological clinics opened.

**NORTH STAFFORDSHIRE INFIRMARY**, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for about 250 patients, including Children's wards, and a special department for the treatment of Diseases of the Eye, a special X Ray and Electrical Department, a special department for the treatment of Diseases of the Ear, Nose, and Throat, a special orthopaedic department, and venereal diseases clinics, so that there are excellent facilities for acquiring a practical knowledge of the profession. During the last six years the sum of £35,000 has been spent on new buildings and alterations. A new Out-patient Department, costing £12,000, a new Children's Ward of 30 beds, a new Pathological Department, and a second large Operation Theatre amongst the structural improvements already completed.

The whole institution is now equipped in a thoroughly up-to-date manner. Secretary and House Governor: Mr. W. Stevenson.

**HULL ROYAL INFIRMARY, Hull.**—This hospital contains 256 beds, and since its establishment in 1782 until the erection of the circular wards in 1907 has undergone steady additions and improvements. A branch convalescent home and sanatorium for consumption at Withernsea are special features of the charity.

**LEICESTER ROYAL INFIRMARY, Leicester.**—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 230 beds, and at the Children's Hospital in connexion 70; total 300. A new wing containing 100 beds was recently opened by H.R.H. the Duchess of Argyll, and a new Nurses' Home containing separate accommodation for 100 nurses has also been opened. A reconstruction scheme has been carried out, and £120,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, and a self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Open-air balconies on all three floors are a feature. A central sterilising department has been provided. A new Pathological Laboratory and post-mortem rooms at an estimated cost of £8000 are now in course of construction, also an orthopaedic out-patients department at a cost of £8000, £5000 of which is being provided by the Freemasons of the province as their war memorial. Further additions are in contemplation. A city university will not unlikely be the town's memorial of the war, and a splendid site has just been presented by Mr. J. Fielding Johnson, J.P., an ex-chairman of the Royal Infirmary. There are eight resident medical officers—viz., four house surgeons, one house physician, one assistant house physician, and two dressers. All receive salaries. The dressers are given an honorarium. House Governor and Secretary: Mr. Harry Johnson.

**NORTHAMPTON GENERAL HOSPITAL, Northampton.**—Two new wings were opened in 1904 and the old buildings entirely renovated and rearranged. The number of beds is 298, 120 of which are occupied by wounded soldiers. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10s. Pupils can be received at any time. An up-to-date Pathological Laboratory is now being erected.

**NORFOLK AND NORWICH HOSPITAL, Norwich.**—This hospital has at present 350 beds. There is a convalescent home at Cromer, and a large staff of visiting nurses is maintained. Secretary: Mr. F. Inch.

**NOTTINGHAM GENERAL HOSPITAL.**—At the present time there are 233 beds available for civilian patients. The accommodation of sick and wounded soldiers from overseas was a great feature at this hospital, which is fully equipped in every branch of medicine and surgery.

**SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.**—This hospital contains 183 beds (12 of which are for Venereal Diseases in a separate building). There is also an Out-patient Venereal Diseases Clinic.

**THE ROYAL HOSPITAL, Portsmouth (founded 1847).**—The number of beds is 160. The hospital has X Ray and Massage Departments. The hospital is a preparatory School of Medicine and Surgery; the attendance of pupils at this hospital is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

**ROYAL BERKSHIRE HOSPITAL, Reading.**—This hospital, which contains 220 beds, has been recently enlarged, the additions including a new Out-patient Department, a Casualty Department, an X Ray Department, a Laboratory, an Eye Theatre, and Eye Wards.

**SALISBURY GENERAL INFIRMARY, Salisbury.**—This hospital contains 145 beds. In-patients, 160 daily average; out-patients, 550, including ophthalmic cases 185 and X Ray cases 1073; attendances on 4683 casuals. Secretary, Mr. S. B. Smith.

**ROYAL SALOP INFIRMARY, Shrewsbury.**—This hospital has 160 beds. In-patients, 1472; out-patients, 1030; out-patients' attendances for the year, 16,542. Secretary: Mr. Alfred Sugden.

**ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL, Southampton.**—This hospital contains 130 beds. In-patients, 1969; out-patients, 7843. Secretary: Mr. T. A. Fisher Hall.

**STAFFORDSHIRE GENERAL INFIRMARY, Stafford.**—This hospital has 80 beds. In-patients, 854; out-patients, 2205. Secretary: Mr. R. Battle.

**ROYAL HANTS COUNTY HOSPITAL, Winchester.**—This hospital has 160 civilian beds. Secretary: Mr. Herbert Maslen.

**WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.**—There are 262 beds. Special departments for Children, Gynaecology, Ear, Throat, and Nose Diseases, Electro-therapeutic and X ray and Pathological departments. There is an excellent library. The resident officers are a resident medical officer and three house surgeons. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a practical knowledge of their profession. A course of Practical Pharmacy is given by the dispenser. Fees on application. Applications should be made to the Secretary of the Medical Committee.

**WORCESTER GENERAL INFIRMARY, Worcester.**—This hospital has 132 beds (temporarily reduced to 70). Pupils are taken by members of the Honorary Medical and Surgical Staff. Number of operations last year 891. New X Ray and Electrical Departments have been recently erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII. In-patients, 966; out-patients, 2990. Secretary: Mr. E. J. Holland.

**YORK COUNTY HOSPITAL, York.**—This hospital contains 170 beds. There are balconies for outdoor treatment and two installations of X Ray apparatus. A Venereal Diseases Clinic is held.

**SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.**—The subjects of the Qualifying examination of the Pharmaceutical Society (for registration as "chemist and druggist") are botany, chemistry and physics, materia medica, pharmacy, and pharmacy law. Fee, 12 guineas; for each subsequent examination after failure, 3 guineas. The advanced or Major examination (for registration as "pharmaceutical chemist") includes botany, chemistry and physics, practical chemistry, and materia medica. Fee, 3 guineas. The inaugural address will be delivered on Wednesday, Oct. 1st. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges and by the University of London. Application for admission to the school, or for further information, may be made to the Dean, Professor Greenish, 17, Bloomsbury-square, London, W.C.1. There are no vacancies for October, 1919.

**THE TRAINING OF MASSEUSES.**—In order to meet the need for a more thorough training of masseuses, and to secure in the future a uniform course of instruction in massage and medical gymnastics, it has been decided by the Council of the Incorporated Society of Trained Masseuses that from Sept. 1st no new schools will be recognised as teaching centres by the Council unless the school authorities undertake to give not less than one year of training (48 weeks). No new teacher of massage will be accepted by the Council unless he or she hold the Society's certificates, or other specially approved certificates. From Jan. 1st, 1921, no candidate will be admitted to the Society's examinations unless they have fulfilled one year of training.

**DEATH OF DR. W. H. PEILE.**—William Hall Peile, M.A. Cantab., M.A., M.D. Dub., L.R.C.P., M.R.C.S., D.P.H., died recently at his residence, Sidmouth, Devon, in his fifty-first year, after a long illness. Dr. Peile was formerly medical officer of health for Sidmouth, and did much useful work in connexion with the housing question, and was largely instrumental in bringing about the erection of 48 cottages in Sid Park-road. He was greatly respected and esteemed, especially among the poor, to whom he was always kind and generous. The funeral was largely attended, the deceased's brother, Bishop Peile, being one of the officiating clergy.

## II.—SCOTLAND.

## THE UNIVERSITIES.

## UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least 100 lectures, or 50 lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months, and courses of instruction in all the subsidiary subjects. They must have personally conducted, under the superintendence of a registered medical practitioner, 20 cases of labour at least.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than one-half must be taken in the University of Edinburgh, which corresponds to the two years above referred to.

Women are admitted to graduation in medicine under practically the same conditions as men.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2s., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6s.; for the Second Division (Anatomy and Physiology), £5 5s.; for the Third Division (Pathology and Materia Medica and Therapeutics), £4 4s.; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Gynaecology, and Forensic Medicine and Public Health), £7 7s.

*Bachelors of Medicine* and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £15 15s., and the fee to be paid for the degree of Ch.M. is £15 15s.

A diploma in Tropical Medicine and Hygiene (D.T.M. and H.) is granted to graduates in Medicine and Surgery of the University of not less than six months' standing, and to Registered Medical Practitioners who, having resided in a tropical country, may be approved by the Senatus, on the recommendation of the Faculty of Medicine.

*Diploma in Psychiatry.*—Courses of instruction have also been instituted for a Diploma in Psychiatry, open to all

legally qualified Medical Practitioners who conform with the Regulations. There shall be two examinations for the Diploma, the first comprising the subjects of Anatomy of the Nervous System; Physiology, Histology, and Chemistry of the Nervous System; Pathology of the Brain and Nervous System; and Practical Bacteriology in its relation to Mental Diseases; and the second examination comprising the subjects of Psychology with Experimental Psychology, Clinical Neurology, and Psychiatry (systematic and clinical). The fee for each examination shall be £5 5s.

*Diploma in Public Health* (D.P.H. Univ. Edin.)—Courses of instruction are also being instituted as from October next for a Diploma in Public Health.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars can be obtained from the Dean of the Medical Faculty.

**SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.**—The number of students varies much in the classes and subjects. It is within the limit to say that before the war about 1000 students availed themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The practical classes and laboratories will open and the lectures commence on Oct. 7th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Special courses of instruction for dental students are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £130, payment of which is distributed over the period of study. There is no composition fee.

Further particulars regarding the school, also its calendar, may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

*Clinical Instruction.*—**ROYAL INFIRMARY, Edinburgh.**—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medico-Electrical and X Ray and Bathing Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 1s. Separate payments amounting to £12 12s. entitle the student to a life ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH, 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 p.m. for outdoor Ear, Nose, and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Secretary: Mr. J. P. Watson, W.S., 33, Charlotte-square.

*Post-Graduate Instruction*—In connexion with the University and Royal Colleges post-graduate courses of lectures in medicine have been arranged for the special needs of graduates returned from active service on demobilisation. These courses are open to women. Three courses have been arranged. Courses in Clinical Medicine and Clinical Surgery are conducted during each of the academic terms, the next commencing on Oct. 14th, and the Winter Term (January to March) commencing Jan. 6th, 1920. A course in Obstetrics, Gynaecology, and Child Welfare is conducted during the summer vacation (August and September) only. As the work of each course occupies the greater part of each day only one course can be taken at a time. The instruction is given conjointly by the Professors in the Faculty of Medicine, the University lecturers and assistants, the lecturers in the Extra-Mural School, and the members of the honorary staffs of the hospitals. The course in Clinical Medicine includes a series of daily lecture-demonstrations on General Medicine, Medical Diseases of Children, Tuberculosis, Medical Ophthalmology, Neurology, Dermatology, Infectious Diseases, Mental Diseases, &c. Arrangements are made by which members of the course may follow the general medical practice of the Royal Infirmary and Royal Hospital for Sick Children in the wards and out-patient departments. Those members of the course who desire to concentrate their attention on a special subject may, by arrangement, be attached as extra clinical assistants in the medical wards of the Royal Infirmary, the Royal Hospital for Sick Children, the Royal Victoria Dispensary for Tuberculosis, the Eye Department or the Skin Department of the Royal Infirmary. Provision is also made for practical instruction in Applied Anatomy, Physiology, Pathology, Bacteriology, and a limited number of members of the course may, by arrangement, act as assistant-demonstrators in the practical classes on these subjects under the professors and lecturers. Members who desire to act as Demonstrators in practical classes and Clinical Assistants in special departments are allocated to these in order of application up to the number of vacancies. Similar provisions are made for the courses in Clinical Surgery and in Obstetrics, Gynaecology, and Child Welfare.

The fee for each of the two first courses is 25 guineas, including hospital tickets, and for the third course 20 guineas. All particulars may be had on application to the Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

#### UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Six degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; and B.Sc. in Pharmacy. A Preliminary Examination must

be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, or Italian, with possible options to students whose native language is not English. Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination, but must do so at not more than two occasions.

*For the degrees of M.B. and Ch.B.* a curriculum of five years is required. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases peculiar to Women and to Infants.

*The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery)* are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

*Fees.*—The Fees for M.B. and Ch.B. are £23 2s. The class fee in each subject of the curriculum for M.B. and Ch.B. is £2 2s., £3 3s., or £4 4s., and the present fee for hospital attendance is £7. The fee for M.D. is £15 15s., and for Ch.M. £15 15s.

The great majority of the students take their hospital course at the Western Infirmary, or the Royal Infirmary, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, and Insanity. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary.

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical

students who have gone through the Arts course. A full list will be found in the University Calendar.

**THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.**—Courses are given which qualify for all the licensing boards and for the Universities of London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are also conducted in the Anderson College of Medicine.

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men.

The Carnegie Trust extends its benefactions to students of the Anderson College of Medicine. Full particulars may be obtained from Sir W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Hugh Cameron, M.A., F.R.I.S., Educational Institute Office, 34, North Bridge-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Walter Hurst, Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

The Winter Session will open on Monday, Oct. 13th, 1919, and will close on Thursday, March 18th, 1920.

The Summer Session will open on Wednesday, April 21st, 1920, and will close on Wednesday, June 30th, 1920.

**ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.**—The classes in St. Mungo's College qualify for the English, Scotch, and Irish Conjoint Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. The classes are open to male and female students equally. The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £100. Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

**QUEEN MARGARET COLLEGE (Women's Department of the University).**—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University. Over 300 women have now taken the degree of M.B., C.M., or M.B., Ch.B. of the University of Glasgow and 24 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill, Queen Margaret College, and the Royal Infirmary. Excellent facilities for clinical work are given in the Royal Infirmary, in the Maternity, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. The Winter Session

will open on Oct. 14th, but owing to the pressure upon accommodation in classes no new students of Medicine are to be admitted until April, 1920. Applications for entrance at that date should be made before Feb. 1st, 1920.

**ROYAL INFIRMARY, Glasgow.**—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. St. Mungo's College is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, skin, venereal diseases, burns and septic cases. The wards are open to Women Students. At the Out-door Department the attendances in 1918 numbered about 114,000. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 12 house surgeons, having a legal qualification in medicine and surgery, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. The fees are as follows: (a) For hospital practice, including attendance at the out-door department, at the pathological department, post-mortem examinations, and the use of the museum: Perpetual ticket, £7; six months, £2 2s.; three months, £1 1s.; separate payments amounting to £7 7s. entitle the student to a perpetual ticket, on return of previous season tickets; (b) for Clinical Lectures, six months, £3 10s.; three months, £1 15s.; (c) Vaccination, £1 1s.; Pathology, £4 4s.; Bacteriology, £2 2s.

**GLASGOW WESTERN INFIRMARY.**—This hospital adjoins the University of Glasgow. Number of beds upwards of 600. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Teeth, Skin, and Venereal Disease. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course. The fee for hospital attendance is £7, and the fees for clinical instruction are £3 3s. for the Winter Session and £2 2s. for the Summer Session. A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods. Secretary: J. Matheson Johnston, C.A., 87, Union-street.

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Incorporated Society of Trained Masseuses.

**ROYAL HOSPITAL FOR SICK CHILDREN, Yorkhill, Glasgow.**—This institution, which was founded in 1882, consists of: (1) a hospital at Yorkhill containing 204 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 24 cots, opened in 1903. Children treated must be under 12 years of age and suffering from non-infectious diseases. In the hospital about 5000 children are treated annually. In the Out-patient Department over 12,000 are treated annually, involving nearly 50,000 attendances. In the present year two lectureships in the University of Glasgow have been founded in connexion with the hospital, one on

the Medical Diseases of Infancy and Childhood, and the other on Surgery and Orthopaedics in Relation to Infancy and Childhood. These lectureships are held by the Visiting Physician, Dr. Leonard Findlay, and the Visiting Surgeon, Mr. Alexander MacLennan. The lectures are both systematic and clinical, but particularly and chiefly the latter. Information with regard to clinical instruction, lectures, demonstrations, &c., may be obtained from the Medical Superintendent.

GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL, Rottenrow.—The new hospital, which was opened in 1908, is in point of size the largest of its kind in Britain and has accommodation for 108 patients. A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Ante-natal Department and an Infant Consultation Clinic. In 1918 2158 normal cases and 1369 abnormal cases were treated by the hospital in the In-door and Out-door Departments. Secretary: Mr. William Guy, 146, Buchanan-street. Full particulars as to fees and accommodation may be obtained from the House Superintendent at the Hospital.

THE ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.—This hospital, founded in 1886, is one of the largest purely gynaecological hospitals in Great Britain, possessing, as it does, over 90 beds. It offers excellent facilities for clinical instruction in the diseases peculiar to women, treating in the wards and in the out-patient department some 4000 cases per annum. The surgeons, four in number, visit the wards in the mornings. For further information application may be made at the Hospital, or to Thos. Macquaker, honorary secretary, 89, West Regent-street, Glasgow.

GLASGOW LOCK HOSPITAL, Rottenrow.—The Hospital contains 83 beds. During 1918 426 patients were admitted to the wards; 9109 visits were made by out-door patients at the Dispensary. Classes are held for the clinical instruction of medical students and practitioners.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (29 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 812; out- or dispensary patients, 13,927; total attendances, 31,553. Operations on Wednesdays and Saturdays. This institution is the Ophthalmic Department of the Royal Infirmary. Clinical instruction is given during both summer and winter sessions to men and women students attending the University. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 26,837 and the total number of cases in 1918 was 27,303. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October. A Post-graduate Class will be held.

GLASGOW HOSPITAL FOR DISEASES OF THE EAR, NOSE, AND THROAT, 27 and 28, Elmbank-crescent.—12 beds and two cots. New patients, 4096. Attendances at out-patient department 16,188. Admitted to in-door department 331. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School. A course of post-graduate study has been conducted by the staff of the hospital. Secretary: Mr. P. T. Young.

#### UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE, ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (I.D.S.). The whole curriculum may be taken at University College, Dundee, or the first two years of the course may be taken at St. Andrews and the remaining three years in Dundee. The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical studies each student shall pass a Preliminary Examination

in (a) English, (b) Latin, (c) Elementary Mathematics, and (d) one of the following optional subjects: (a) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other approved Modern Language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of LL.A.

*Degree of Bachelor of Medicine and Bachelor of Surgery.*—Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants. Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anesthetics, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

*Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.*—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica and Pathology and Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynaecology (Systematic and Clinical).

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 15 guineas, and for the degree of Master of Surgery 15 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews.

For further particulars and details as to scholarships and bursaries application should be made to Professor Kynoch, Dean of the Medical Faculty, University College, Dundee.

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

ROYAL INFIRMARY, Dundee.—The Infirmary contains 408 beds, including special wards for the Diseases of Women, Children, Eye, Ear, and Throat, Skin, and for Obstetric cases. There is in addition an Extern Obstetric Department. There were during last year 13,895 out-patients and 471 home (maternity) patients. The Royal Infirmary offers facilities for practical work to students. Appointments: Six qualified Resident Medical Officers (Male or Female) are appointed every six months and one Obstetric Assistant. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica. Further information can be obtained from the Medical Superintendent.

#### UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.).

*Degrees of M.B. and Ch.B.*—Before commencing his medical studies each student must pass a Preliminary Examination in (1) English, (2) Latin, (3) Mathematics, and (4) Greek, or French, or German. The curriculum for the degree extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital; they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem examinations, Venereal Diseases, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

The fee for the degrees of M.B. and Ch.B. amounts to £23 2s.

Besides the Royal Infirmary (270 beds), students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institution, &c.

*Degrees of M.D. and Ch.M.*—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty.

*Scholarships and Prizes.*—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £160 per annum. Prizes and Medals: 13 Gold Medals and Prizes for proficiency in special departments, &c.

*Clinical Instruction* is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff.

ABERDEEN ROYAL ASYLUM.—Contains, with hospital attached to main institution and agricultural branch, about 986 beds. Clinical instruction is given to students during three months in summer. Clerk and Treasurer, Mr. A. Scott Finnie, 343, Union-street, Aberdeen.

#### SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

*Professional Education.*—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months; Practical Physiology, three months; Materia Medica, three months; Pathology (including Practical Pathology), nine months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months; Gynaecology, one course of not less than 13 meetings; Diseases of Children, one course of not less than 13 meetings. Medical Jurisprudence and Public Health, three months. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or act for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; Gynaecology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

*First Examination* includes Physics, Chemistry, and Elementary Biology.

*Second Examination* includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

*Third Examination* includes Pathology and Materia Medica with Pharmacology.

*Final Examination.*—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c. The fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject.

There are four periods of examination annually during the present reconstruction period, two in Edinburgh and two in Glasgow, in 1919-20. The Registrar in Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom further particulars concerning fees can be obtained.

#### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

*Membership.*—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University within the British Empire, approved by the Council and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynaecology, diseases of children, tropical medicine, or medical jurisprudence. The fee for the Membership is £36 15s., 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

*Fellowship.*—The Fellows are selected from the ranks of the *Members*. The fee is £64 18s.

#### ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Colonial university or of any British or Colonial College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are now admitted to the Licence of the College but not to the Fellowship, and the regulations for the Licence apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees or diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

*The Fellowship.*—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly *viva voce*, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiate of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to present himself for examination must be given by the candidate to Mr. D. L. Eadie, 49, Lauriston-place, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, unless a special application, with testimonials, be made to the President and the Council of the College.

#### THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held as separate qualifications.

*Fellowship.*—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. 14 days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £30, £10 of which sum are returned to any successful candidate who already holds the Licence of the Faculty. An additional sum of £20 is required in the case of candidates resident within seven miles of Glasgow. In certain circumstances Fellows may be elected as a mark of distinction.

*Licence.*—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

#### SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

The hospitals which are recognised by the Scottish Conjoint Board, as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 379) and the Irish Conjoint Board (see p. 391).

### III.—IRELAND.

#### THE UNIVERSITIES.

##### UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

*Matriculation.*—In order to join the School of Physic students pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 1st.

*Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).*—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Systematic, Descriptive and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics and Practical Physics, Physiology and Practical Physiology, Practice of Medicine, Midwifery, Pathology, Materia

Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 30 cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy and Physiology. The Intermediate Medical, Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., *Materia Medica*, Hygiene and Jurisprudence, and Pathology; and Part II., Medicine, including Clinical, Surgery, Midwifery, Gynaecology, Mental Diseases, Operations, and Clinical Ophthalmology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth year.

*Doctor in Medicine.*—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also read a thesis before the Regius Professor of Physic.

*Master in Surgery.*—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

*Master in Obstetric Science.*—A Master in Obstetric Science must be a Bachelor of two years' standing and produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

*Diploma in Gynaecology and Obstetrics.*—A post-graduate is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital and a six months' course in Trinity College when they have passed a special examination.

*Bachelor in Dental Science and Master in Dental Science.*—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

*Clinical instruction.*—The hospital facilities for clinical instruction available in Dublin will be described below.

#### THE NATIONAL UNIVERSITY OF IRELAND.

*Matriculation.*—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres. All students must pass in five subjects (three of which must be Irish, English, and mathematics). All students must pass in Irish<sup>1</sup> except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French,

German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate. History and Geography (*as a composite subject*), Natural Philosophy, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology, and Hygiene. Candidates who under the regulations are exempted from the necessity of presenting Irish as one of their subjects may present as their fifth subject either a second language or a second science subject. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, may be accepted as matriculated students of the Faculty of Medicine on passing the matriculation examination in any faculty of the University.

The medical degrees granted are:—

*M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O.*—

Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908. Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College. The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and co-opted lecturers, a body of graduate members, and a body of student members matriculated in the University. The first professors and lecturers were appointed by the Dublin Commissioners Irish Universities Act, 1908.

*Matriculation.*—Almost all the students of the College are matriculated students of the National University of Ireland.

*University Examinations in Medicine.*—The First Examination includes Physics, Chemistry, Botany, and Zoology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and *Materia Medica*.

*Degrees of M.B., B.Ch., and B.A.O.*—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year when the curriculum has been completed. The course of study is as follows:—First year.—Winter: Anatomy and Practical Anatomy (required for the Second Examination), Chemistry, Practical Chemistry, and Experimental Physics (with Laboratory Course). Summer: Zoology, Practical Zoology, Botany, and Practical Botany. Second year.—Winter: Anatomy, Practical Anatomy, Physiology, and Practical Physiology (physical and chemical). Summer: Anatomy, Practical Anatomy, Physiology, and Practical Histology. Third year.—Winter: Pathology, Surgery or Medicine, Hygiene, Medical Jurisprudence, and Practical Pharmacy. Summer: *Materia Medica* and Therapeutics, and Practical Pathology. Candidates are also required to attend a General Hospital for nine months (winter and summer). Fourth year, or fourth and fifth years.—Winter: Medicine or Surgery (the subject to be that not taken in the third year), and Midwifery and Gynaecology. Summer: Operative Surgery, Applied Anatomy, and Ophthalmology and Otology. Candidates are also required to attend a General Hospital for nine months (winter and summer), and to take instruction in Vaccination, and three months Fever Hospital. Fifth year.—If the Academic (Cillegiate) Courses are taken as above, the Courses of the fifth year will be the following: Hospital Attendance, General Hospital, nine months; Clinical Ophthalmology and Otology, three months; Practical Midwifery and Gynaecology, six months; Mental Diseases, to be attended at a Lunatic Asylum, three months. (Note.—Practical Midwifery and Gynaecology may be taken in

<sup>1</sup> The Senate has directed that candidates who presented themselves for the Matriculation Examination and who passed in certain subjects in 1912 or any previous year, may, when presenting themselves in 1920, in the remaining subjects necessary to complete the examination, select such completing subjects in accordance with the regulations as to groups of subjects which were in force in 1912. Such candidates will not be obliged to present themselves for examination in Irish. Such candidates, however, while they may select the completing subjects as above, must present themselves for examination in these subjects on the courses prescribed in each by the Regulations in 1920. Candidates who presented themselves for the Matriculation Examination, and who passed in certain subjects in 1913, when presenting themselves in 1920 in the remaining subjects necessary to complete the examination, must select such completing subjects in accordance with the regulations as to groups of subjects which were in force in 1913. The courses in such completing subjects will be the courses prescribed in those subjects respectively for 1920.

the fourth year after the Systematic Course of Midwifery but it must not be taken concurrently with the period of attendance at Fever Hospital.) The degree of M.D. may be obtained either by examination or on published work.

*Fees.*—The fees for Courses are similar to those of the other Dublin Medical Schools.

Information concerning these, and the numerous scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Professor E. P. McLoughlin.

#### UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.

—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains over 50,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting once in each year in the Mardyke grounds.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who may be candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council. Candidates will be examined in Irish, Greek, or French or German, Latin, History, Geography, English, and Mathematics.

*Admission of Medical Students.*—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may be admitted to the rank of fourth-year students.

*Residence of Students.*—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

*Clinical Instruction.*—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, the Cork Fever Hospital, the Cork District Hospital, and the Cork Ear, Eye, and Throat Hospital.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the College, Professor A. E. Moore.

*South Infirmary and County of Cork General Hospital* (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for perpetual ticket, £22 1s.; for nine months, £9 9s.; for six months, £6 6s.; for three months, £3 3s. Two resident pupils will be appointed by competitive examination. Honorary Secretary: Dr. N. I. Townsend.

*Cork North Charitable Infirmary and County and City of Cork General Hospital* (112 beds).—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior Students on two days weekly. Fee for perpetual ticket, £22 1s.; for 12 or nine months, £9 9s.; for six months, £5 5s.; and for three months, £3 3s. Two resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, under the charge of Mr. J. Bowring Horgan, and a special dental department. Honorary Secretary: Mr. R. B. Dalton. A fully equipped Pathological Department has recently been added to the hospital.

*Mercy Hospital.*—This hospital contains 130 beds for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical attendances for 1917 and 1918, 10,935; surgical attendances, 2361; eye, ear, nose, and throat attendances, 7200; intern patients 1918, 1558. Major operations, 698; minor operations, 643. Minor accidents, 3310. Total extern free attendances, 36,105. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor.

*Cork District Lunatic Asylum.*—Psychological Medicine: A course of Clinical Lectures on Mental Disease and Allied Neuroses will be delivered in the Cork District Lunatic Asylum on Mondays and Thursdays, commencing the first Thursday in May, by the Resident Medical Superintendent. All students wishing to enter for the course are expected to attend at the Asylum at 4 P.M. on that day. All information may be had at the Asylum from the resident medical superintendent.

*Victoria Hospital (Incorporated)* (Cork).—There are 75 beds. Clinical instruction on Diseases Peculiar to Children is given. The extern department is open daily at 9.30.

*County and City of Cork Lying-in Hospital* (Erinville, Western-road; founded 1798).—This hospital contains 22 beds, an Extern Midwifery Department, Gynaecological Department, Extern Department for Women, and Child Welfare Centre. Fee for six months' attendance, including clinical lectures, £3 3s. For further particulars apply to Lucy E. Smith, M.D., secretary to staff.

*Cork Maternity* (Batchelor's Quay).—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate, £3 3s. Honorary secretary to staff, Dr. Henry Corby.

*Cork Fever Hospital.*—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

*Cork District Hospital* (Douglas-road; 1200 beds).—This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynaecology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. W. E. Ashley Cummins, 17, St. Patrick's-place, honorary secretary, medical staff.

*Cork Eye, Ear, and Throat Hospital* (Western-road).—This hospital is open to students attending the University College and others. Certificates of attendance for three or

six months can be obtained. The hospital contains 35 beds. Over 4000 cases are treated during the year. A course of Lectures on Ophthalmic Surgery is delivered during the session. For further information apply to Dr. Arthur Sandford, 13, St. Patrick's-place, Cork.

#### UNIVERSITY COLLEGE, GALWAY: SCHOOL OF MEDICINE.

—The College contains a well-lighted and ventilated dissecting-room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynaecological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £25 each, for which Medical Students compete with other Students on the Entrance Course. In the Second, Third, and Fourth Years three Scholarships in each year, value £25 each, are reserved for Medical Students. Exhibitions of £10 and £5 are awarded on results of 1st, 2nd, 3rd, and Degree Examinations in Medicine. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

*Clinical Instruction* is given in the Galway Hospital and in the Galway Union and Fever Hospitals, containing on an average 200 patients.

*Galway County Hospital* (62 beds).—Founded by Act of Parliament.

*Galway Union and Fever Hospitals* (150 beds).—Clinical instruction is given in these hospitals to the Medical Students of University College, Galway. The regulations for Scholarships tenable in the College, and the regulations for degrees and for courses can be obtained from Messrs. O'Gorman and Co., Galway.

#### QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for

that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

*Primary Degrees of M.B., B.Ch., B.A.O.*—All candidates for these degrees must satisfy the examiners in the subjects of four examinations known as the First, Second, Third, and Fourth Medical Examinations respectively.

*The First Medical Examination.*—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

*The Second Medical Examination.*—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

*The Third Medical Examination.*—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

*The Fourth Medical Examination.*—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otolaryngology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

*Degrees of M.D., M.Ch., and M.A.O.*—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (a) after an examination, which includes written, oral, clinical, and practical examinations; or (b) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject thereof.

*The Medical School.*—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is

in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

*Clinical instruction.*—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Pardysburn Fever Hospital, and the Belfast District Lunatic Asylum.

*The Royal Victoria Hospital* (300 beds).—Women students are now admitted as resident medical pupils the same as men.

*Mater Infirmorum Hospital* (200 beds).—Honorary Secretary Medical Staff: Mr. J. B. Moore.

*Belfast Union Infirmary and Hospital* (1700 beds).—Clinical courses are given biannually, and Course for D.P.H. in Hospital. Intern. Venereal Clinic in Infirmary under Corporation Scheme. Particulars may be obtained on application, as to classes, to Dr. McLiesh.

*Hospital for Sick Children*, Queen-street (52 beds).—Honorary Secretary, Medical Staff: John McCaw, M.D.

*The Incorporated Belfast Maternity Hospital*, Townsend-street (32 beds).

*Ulster Hospital for Children and Women* (44 beds).

*Benn Ulster Eye, Ear, and Throat Hospital* (30 beds).

*Belfast Ophthalmic Hospital*, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and Laryngology. Clinical instruction is given daily. Fee for three months £2 2s.

*Belfast Fever Hospitals.*—City Fever Hospital, Pardysburn (330 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-Graduate (D.P.H.) Classes are also held.

*Belfast District Lunatic Asylum* (1250 beds).

## IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

*The Licence in Medicine.*—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

*The Licence in Midwifery.*—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

*The Membership.*—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15s. to non-Licentiates. Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, Kildare-street, Dublin.

*The Fellowship.*—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

### ROYAL COLLEGE OF SURGEONS IN IRELAND.

*The Licence in Surgery.*—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery.

*Diploma in Midwifery.*—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

*Fellowship Examinations.*—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (a) Anatomy, including Dissections; and (b) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars as to fees and conditions of examination can be obtained from the Registrar of the College, Stephen's-green, West Dublin.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence of having before entering on medical studies passed a Preliminary Examination in general education recognised by the Royal Colleges. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of 21 years.

*Preliminary Examination.*—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

*Professional Examinations.*—Every candidate must pass four Professional Examinations—at the end of the first, second, third, and fifth years respectively of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body.

*First Professional Examination.*—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; and (2) of having attended a course of—(a) lectures on Theoretical Chemistry, six months; (b) Practical Chemistry, three months; (c) Biology, three months; and (d) Physics.

The subjects of the First Professional Examination are the following:—1. (a) Chemistry; (b) Physics. 2. Biology. The fee for this examination is £15 15s.

*Second Professional Examination.*—Candidates are not admissible to this examination till they have passed in the subjects of the First Professional Examination, and they must produce evidence of having attended (a) anatomical dissections, six months; and Lectures on (b) Anatomy, six months; (c) Physiology, six months; (d) Practical Physiology and Histology, three months.

The subjects of the Second Professional Examination are the following:—(1) Anatomy; and (2) Physiology and Histology. The fee for this examination is £10 10s.

*Third Professional Examination.*—Every candidate is required, before admission to the Third Professional Examination,

tion, to produce evidence of having passed the Second Professional Examination, and certificates of having attended courses of instruction in (a) the practice of a medico-chirurgical hospital for nine months; (b) Pathology—(1) Systematic, (2) Practical, three months each; (c) Materia Medica, Pharmacy, and Therapeutics, three months; (d) Forensic Medicine and Public Health, three months. The subjects for the Third Professional Examination are the following:—(1) Pathology; (2) Materia Medica, Pharmacy, and Therapeutics; (3) Public Health and Forensic Medicine. The fee for this examination is £9 9s.

**Final Professional Examination.**—Before admission to the Final Examination candidates must have passed the Third Professional Examination and produced evidence of having attended in Division I. the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission in Division II.); the practice of a recognised fever hospital or the fever wards of a recognised clinical hospital, three months; clinical instruction in Mental Diseases, one month (12 attendances); lectures on Medicine, six months at a recognised medical school; of having performed the duties of medical clinical clerk in a recognised hospital for three months; of having attended a course of instruction in post-mortem examinations and demonstrations during one session. In Division II. of having attended the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission to Division I.); clinical instruction in Ophthalmic and Aural Surgery, three months; lectures on Surgery, six months at a recognised medical school; instruction in Operative Surgery, three months at a recognised medical school; of having performed the duties of surgical dresser in a recognised hospital for three months; of having attended a course of instruction in the practical administration of general anaesthetics. In Division III. of having attended a midwifery hospital or maternity and having been present at 20 labours, six months; instruction on vaccination, six attendances to be certified by a public vaccinator; lectures on midwifery (including diseases peculiar to women and to new-born children), six months at a recognised medical school. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the Divisions I., II., or III., provided he has completed his curriculum as far as concerns the division in which he presents himself. The examination in at least one of the divisions must be deferred till the end of the fifth year.

The subjects of the Final Examination are: (1) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (2) Surgery, Operative and Ophthalmic; and (3) Midwifery and Gynaecology, Vaccination, and Diseases of New-born Children. The fee is £6 6s. Further particulars can be obtained from Alfred Miller, the Secretary of the Committee of Management, Royal College of Surgeons, Stephen's-green, Dublin.

**ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).**—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5s.; H. Macnaughton-Jones gold medal in Obstetrics and Gynaecology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green, W., Dublin.

#### APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are three professional examinations, the total fees for which amount to 30 guineas. Women are eligible for the diploma.

There are four examinations—primary, intermediate, Parts I. and II., and final. They are held three times a year, in March, June, and December. The primary examination comprises biology, physics, theoretical and practical chemistry (with an examination at the bench). Candidates holding a Pharmaceutical licence are exempt from this subject. Intermediate, Part I., Anatomy and Physiology. Intermediate, Part II., Pathology, Medical Jurisprudence, and Materia Medica and Pharmacy. The intermediate examination comprises anatomy of the whole body (including practical dissections), physiology, practical histology, and materia medica. The final examination comprises medicine, surgery, and midwifery.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary-street, Dublin.

#### HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.<sup>1</sup>

**ADELAIDE HOSPITAL**, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12s.; six months, £8 8s. Summer, three months, £5 5s. Two resident surgeons are elected yearly and four resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Dermatology will be awarded.

**Hudson Scholarship.**—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in medicine, surgery, gynaecology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Dr. H. Bewley.

**COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN**, Dublin.\*—This hospital contains nearly 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland. Lectures are delivered, practical instruction given, and gynaecological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynaecology is given. There is no extra charge for attendance at this dispensary. There is accommodation for intern pupils who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. The residents' quarters are comfortable. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Fees: Extern pupils for full course of six months, £8 8s.; three months, £4 4s. Intern pupils, one month, £4 4s.; each consecutive month, £3 3s.; six months, £18 18s.; board and lodging in the hospital, 25s. per week. Lady students, intern, one month, £4 4s.; each consecutive month, £3 3s. Registration fee, in advance, 10s. 6d. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the hospital.

<sup>1</sup> This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in Belfast, Cork, and Galway have been described in connexion with the Belfast and National Universities.

\* No returns.

**SIR PATRICK DUN'S HOSPITAL**, Grand Canal-street, Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Six Resident Pupils are appointed each half-year. Six Surgical Dressers and six Clinical Clerks are appointed each month. There are facilities for women students.

*Prizes and Medals.*—Clinical medals and prizes amounting to about £15 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

*Fees.*—Winter and summer session, £12 12s.; winter session (six months), £8 8s.; and summer session (three months), £5 5s. Special certificate in anaesthetics, £1 1s. The practice of this hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

Further information will be supplied by the Hon. Secretary to the Medical Board.

**JERVIS-STREET HOSPITAL**, Dublin.—Founded 1718; rebuilt 1886. 130 beds. A new out-patient department has been completed and contains all modern requirements. Secretary: Mr. Kieran O'Dea.

**MATER MISERICORDIE HOSPITAL**, Dublin.\*—This hospital, the largest in Ireland, containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical Operations will be performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Three House Physicians, six House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. A Private Hospital has been opened for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses have been opened in connexion with the Hospital.

*Terms of attendance.*—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Medical Board, Mr. A. Blayney, 15, Merrion-square.

**MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.**—This hospital was founded in 1753 and now contains 166 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Six Medical Clinical Clerks and 12 Surgical Resident Pupils and Dressers are appointed every six months, and House Surgeons and Clinical Assistants are elected annually. A prospectus giving the complete arrangements for the coming session may be obtained from the Honorary Treasurer of the Medical Board, Sir L. H. Ormsby, 92, Merrion-square, Dublin.

**MERCER'S HOSPITAL.**\*—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become

eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients. Students of the hospital are permitted to attend the gynaecological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

*Appointments.*—A House Surgeon is appointed annually. There are Five Resident Pupils, and Clinical Clerks and Dressers are appointed monthly from amongst the most deserving members of the class. Women students are admitted.

*Fees.*—Winter, six months, £8 8s.; Summer, three months, £5 5s.; nine months, £12 12s.

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square, Dublin.

**NATIONAL MATERNITY HOSPITAL**, Holles-street, Dublin.—Established 1894. The Hospital consists of an Intern and Extern Maternity, and a Dispensary for the treatment of Diseases of Women and Children. About 1000 cases are admitted and over 300 operations are performed annually. Every facility is given for the carrying out of practical work. Post-graduate and special courses are arranged for at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Terms (three months' course) 6 guineas. Board 25s. per week. Further particulars can be obtained from the Masters: Sir Andrew Horne, 94, Merrion-square, Dublin; Dr. Reginald J. White, 23, Merrion-square, Dublin; or from the Secretary, Holles-street, Dublin.

**RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS** (HOUSE OF INDUSTRY HOSPITALS), Dublin.—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds for sick soldiers. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 12 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon. Secretary, 69, Fitzwilliam-square, Dublin. The sad pecuniary position of the House of Industry Hospitals is giving much anxiety to the city of Dublin. It seems that they will have to be closed unless the authorities can find means to support them.

**ROTUNDA HOSPITAL**, Dublin.—This institution is the largest combined gynaecological and maternity hospital in the British Empire. Nearly 4000 confinements attended annually. Students can take out their necessary gynaecological and midwifery practical courses. Appointments open to qualified practitioners as Assistant to the Master and Extern Assistants. Women students can reside in the hospital on terms similar to those for men. For further particulars apply to the Master.

**ROYAL CITY OF DUBLIN HOSPITAL.**—Founded 1832; enlarged 1851; rebuilt 1893. 150 beds. There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. Secretary: Mr. Edw. B. Armstrong.

**ROYAL VICTORIA EYE AND EAR HOSPITAL**, Dublin.—Established 1844. Incorporated 1897. 102 beds. In-patients, 1311; out-patients, 9481. Two house surgeons appointed annually.

**DR. STEEVENS' HOSPITAL**, Dublin.—Established 1720. 250 beds. Patients, 12,834. Secretary: Mr. R. J. Ogden.

**ST. VINCENT'S HOSPITAL AND DISPENSARY**, Dublin.—Established 1834. 200 beds.

WE have received from the Deans and Secretaries of the various centres the corrected lists of the teachers at the schools and of the medical staffs of the hospitals at which clinical education is being carried on. We take the opportunity of thanking these officers for their valuable co-operation, as it enables us to keep the lists revised for reference. We hope to publish the lists in an early issue; they are not yet complete.

\* No returns.

# THE LANCET.

LONDON: SATURDAY, AUGUST 30, 1919.

## The Future of the Medical Profession.

THE educational medical year opens in circumstances so uncertain, so involved, and in many directions so difficult for the medical profession, that those for whom the Students' Number is primarily issued may be excused if they can know little of their worldly prospects. Indeed, we think it is well that this should be so; for the greatest driving force which the medical student can possibly possess is his desire to get into the service of healing, whatever the conditions may be. The best student is he whose first object is to gain admission to this service, influenced by the certainty that he may become a power for good, and undeterred by the warnings of self-interest. We are not, however, suggesting that the conditions of medical service are at the moment particularly unpromising, or even ominous, because they happen to be sharing in an all-pervading social muddle. The whole of our advanced civilisation is in flux, and all the world rings with the cries of reorganisation and reconstruction. In every country leaders of men, made to admit by the revelations of the war the many weak joints in their social armour, have resolved that those joints shall be mended or that armour of a new pattern shall be employed. But for the moment there is necessarily more confusion than reconstruction, and, alas! more words than deeds. This cannot be helped. The necessary qualities in these days of transition are hope and belief—hope that the endurance which has carried us through days of trial will be with us in those of reaction, and belief that knowledge will triumph over ignorance, when inequalities will be righted by a general sense of justice. For there is only a certain amount of happiness to go round. That truism, brought home to us by the necessity of maintaining to-day the food control at first instituted as a war measure, is not sufficiently remembered. It is an unfortunate, though pardonable, fact that the protagonists of different reforms, in single-hearted intent to secure along their own lines the best of everything for everybody, postulate the depriving many other people of things essential to prosperity. Such champions of individual views forget that there may not be enough happiness to go round. There has to be throughout the world an immense amount of give-and-take, or what happiness that exists will undergo no fair division. This is universally true; but medicine is, perhaps, more sorely tried than any vocation in the position thus set out, for medicine enters into all the activities of the world, epitomises by its exploits the most

poignant and permanent virtues which citizens can display for the good of others, and probes in its daily life the wants and miseries of all sorts and conditions of men, codifying, evaluating, and, where possible, remedying them. No class like the medical class is so much part and parcel of the intimate lives of everybody else, and, as a consequence, the muddles of all the other sections of the population are reflected in the life of the general practitioner. The medical student must not at the outset of his career allow his equanimity to be disturbed by prophecies of ill in the future or by fables of the resplendent past. He has chosen a high calling for its own sake, and a high calling it must always be. It is our belief, also, that he has chosen a calling whose value to the State is in a better way to receive public and material acknowledgment than heretofore.

He who joins our ranks to-day begins his medical life under the aegis of the Ministry of Health—a new Government Department designed at one and the same time to provide for the people an efficient and orderly medical service and to secure for the members of that service the best means of discharging their important functions. Such a Government Department has long been desired, and it is impossible that its activities should fail to operate in the near future to the advantage of medicine. There is at the present moment in the country a large number of young medical men at a loose end. Many of them are full of new experiences, and they are not finding opportunities for bringing those experiences to market in such a way that they can obtain good terms. The undoubted hardship felt by many of the medical men returning from war to practice must not dash the spirits of the recruits; and those who in this generation are suffering from the helplessness of medicine as an unorganised calling should be ready for united action, which will be of present worth, but whose benefit to future practitioners must be very great. Some genuine form of union is needed: some way by which we can find out what is the right medical view and what is the proper public claim, and can adjust these two things to the common satisfaction. A number of administrative or subadministrative posts, carrying regular salaries, and graded not only in accordance with the importance of the responsibilities incurred, but in accordance with the time to be taken up, will probably come into being soon; and it may be presumed that many of these posts will be part-time offices. Reorganisation of panel practice, which in some directions is imminent, will certainly place at the disposal of young medical men many chances of obtaining an assured livelihood and good scope for general or special clinical knowledge. When the panel practice, over and above the flat-rate payments of subscribers, brings with it a part-time appointment the aggregate emolument will make the young medical man far better paid at the opening of his career than his father or his grandfather could ever have expected to be, had he joined our profession. Hitherto the one

great and condemnatory criticism of the position has been that while the start is so fair the sequel holds no greater promise. In panel practice a man may make almost at the outset what turns out to be his maximum income. It is clear to everyone that in the public employment of the future some flexible system of promotion will have to be laid down, so that the inexperienced man does not receive as much money as his senior. The income from panel subscribers can only go up if the practitioner increases the size of his panel, and while for physical reasons this may be an impossibility for public as well as scientific reasons, it is an undesirable form of success. Justifiable comment on the position of panel practice has always been that the good start does not necessarily ensure the good future, and if we had come as a profession to any common conclusion we should realise that this is the main direction in which panel practice requires reform, once the question of proper emolument has been settled. But the meaning of all this is that general practice in Great Britain, as we have hitherto understood it, is largely in the melting-pot. In a few years' time there may no longer be a group of family practitioners having sole charge of the health of certain districts, each of them supposed to represent all the medical and surgical wisdom required in that district, save where the Ministry of Health, as medical heir to the Local Government Board or the Board of Education, annexes a portion of the burden and therefore of the remuneration. But the destruction of the old-time practices will go hand-in-hand with added opportunity, both for specialisation and for the passage from the ranks of general practice to those of hospital surgeon and physician and scientific expert. For as there will be no segregated class of general practitioner, so there will be no segregated class of hospital officer and scientific expert. The provincial hospitals, becoming centres of scientific medicine in their localities, will be officered by men who, by fusion of duty with the general practitioners of the neighbourhood, will make of the whole of the medical officers one general scheme for the good of the populace. The medical men of the district will have beds in their own hospitals, and will receive for their patients the consultative advice of their fellows and the assistance supplied by a laboratory of chemical research.

This is rather a picture of the future, but it is not so much an imaginary one as the common derivative from many schemes for reconstruction and reorganisation. The new recruits of medicine will be placed in regard to these large changes in a more favourable position than the young practitioners immediately preceding them, whose professional prospects have been so involved with the struggles of war. Our new students, having at least five years to wait before material conditions of life affect them, will find many modifications of practice, amounting to large revolutions, quietly

arranged, and, we hope, for the common good. The difficulty in which the young practitioners who desire to settle down in general practice are now placed is that they have little evidence which developments are inevitable and which will be for their material good. These young men have seen many things and done many things, and while some find the prospect of private practice humdrum, others find it attractive, but the future depressingly doubtful. To these, as to the students of to-day, we suggest that it requires no great spirit of prophecy to say that all things in the social world are working in favour of a properly treated and properly remunerated medical profession. The position of medicine has risen steadily in public esteem, the association of medicine with every form of domestic, national, and international politics alike has become very close, and the demand for medical counsel in every direction will grow keener. The profession must gain in strength under such public support, and it is impossible that the question of emolument can always be decided in the future against medical interests. These things being so, let us remember that while the medical life has many charms, the work to be done is anxious and exacting beyond the reach of adjectives, while the portals of entrance are strictly kept. For this reason, as well as for reasons connected with the suspension during the war of medical education, it will be a long time before there is an over-supply of medical men. At the present moment young men are sorely needed in civil and in official or service circles. The conditions of service in the Army and Navy, Indian Medical Services, and the Colonial Medical Service have been steadily improved into attractive terms. And just as these services cannot very well challenge each other in rates of pay, so their rates of pay must influence civilian rates and maintain a good standard all round. Thus young men who are choosing the medical profession as a career will find that they have chosen wisely, apart from the delight and utility of the life. They are entering a profession which tends to be well paid, and the advent of the Ministry of Health on the scene must turn all the circumstances to the favour of medicine in the end, even though we have a trying time of transition. It is, however, to be regretted deeply that during this time no form of political union among medical men is really effective to help the profession in arriving at proper terms. The British Medical Association, a powerful body, speaks for half the medical profession, but not, and very properly not, in unanimous sense on many questions. The British Federation of Medical and Allied Societies has a brave programme, and if properly supported should gain for the medical profession a sympathetic hearing from the public, but the size and good sense of its design must make a larger appeal to practitioners before its influence can be felt. Some channel through which the current of medical opinion can reach the stream of public action is needed.

## THE NAVAL, MILITARY, INDIAN, AND AIR FORCE MEDICAL SERVICES.

THE conditions of service in the medical departments of the Royal Navy, the Army, and Indian Army have considerably changed for the better since (and previous to the war) we had occasion to give a résumé of those conditions to our readers. It will be seen that in some particulars our account is imperfect, but formal approval has not yet been received for the revised rate of pay in all three services, and in certain places the conditions are open to change. Common sense, however, tells us that an attempt will be made to equalise the rates of pay.

The medical service of the Royal Air Force had, of course, no existence before the war. The conditions here can only be described in general terms.

### ROYAL NAVAL MEDICAL SERVICE.

#### REGULATIONS.

FOLLOWING are the Regulations for the entry of candidates for commissions in the Medical Department of the Royal Navy. A copy of the regulations can be obtained, together with the form to be filled up, on application to the Medical Director-General.

Every candidate for admission into the Medical Department of the Royal Navy must be not under 21 nor over 28 years of age on the day of the commencement of the competitive examination. He must produce an extract from the register of the date of his birth; or, in default, a declaration made before a magistrate, from one of his parents or other near relative, stating the date of birth.

He must declare (1) his age and date and place of birth; (2) that he is of pure European descent and the son either of natural-born British subjects; (3) that he labours under no mental or constitutional disease or weakness, nor any other imperfection or disability which may interfere with the most efficient discharge of the duties of a medical officer in any climate; (4) that he is ready to engage for general service at home or abroad, as required; (5) whether he holds, or has held, any commission or appointment in the public services; (6) that he is registered under the Medical Act, giving the date of his registration as a medical student, or of his beginning professional study; and (7) whether he has previously been examined for entry in the Naval Service, and, if so, when.

The certificates of registration and birth must accompany the declaration, which is to be filled up and returned as soon as possible, addressed to the Director General, Medical Department, Admiralty, London, S.W., to permit of reference to the candidate's medical school. The Dean or other responsible authority of such school will be requested by the Medical Director-General to render a confidential report as to the candidate's character, conduct, professional ability, and fitness to hold a commission in the Royal Navy. The candidate will then be interviewed by the Medical Director-General, and his physical fitness will be determined by a board of Naval Medical Officers. The Medical Director-General will then decide whether he may be allowed to compete. If accepted, the candidate will be eligible to present himself at the entrance examination, which will be held twice a year. Notification of the exact date of this, as well as the number of commissions to be competed for, will be advertised in THE LANCET. Candidates will be examined in the following subjects: (a) Medicine, including Medical Pathology and Therapeutics; and (b) Surgery, including Surgical Pathology and Clinical Surgery. The examination will be partly written and partly practical, marks being allotted under the following scheme:—

Medicine.				Surgery.			
Paper ... ..	400	Paper ... ..	400	Paper ... ..	400	Paper ... ..	400
Clinical ... ..	400	Clinical ... ..	400	Clinical ... ..	400	Clinical ... ..	400
Oral ... ..	400	Oral ... ..	400	Oral ... ..	400	Oral ... ..	400
Total ... ..	1200	Total ... ..	1200	Total ... ..	1200	Total ... ..	1200

No candidate will be considered eligible who obtains less than 50 per cent. of marks in each subject. The examination will be held in London and will occupy four days.

The appointments announced for competition will be filled from the list of qualified candidates, arranged in order of merit; but should it at any time be considered expedient to grant Commissions beyond those periodically competed for, the Admiralty have power to admit annually not more than six candidates, according to requirements, specially recommended by the governing bodies of such Colonial Universities as may be selected and whose qualifications are recognised by the General Medical Council. Candidates so proposed are to be approved by the Director-General of the Medical Department of the Navy. Colonial candidates will have to pass a physical examination before a board of Naval Medical Officers in their colony, and will be required to register their qualifications on arrival in England. They will be allowed, if they wish it, to compete at the next examination for entrance and take their position according to the order of merit; should they decide not to compete they will be placed at the bottom of the list. It will, however, be necessary in any case for them to pass a qualifying test at the time of the usual half-yearly examinations, when they will be required to obtain a minimum of 50 per cent. of the total marks in each subject. In case of failure in this test examination the Admiralty will not undertake to defray the cost of the return journey to the candidate's colony or other expenses thereby incurred. A fee of £1 will have to be paid by each candidate to entitle him to take part in the competition.

Candidates who have served in the Officers Training Corps, and who are in possession of the certificates laid down in the regulations for

that Corps, will be credited at the entrance examination with additional marks as follows: Candidates in possession of Certificate A will receive 1 per cent., and those who possess Certificates A and B 2 per cent. of the maximum number of marks allotted.

A candidate will not be allowed to compete at more than two examinations.

A candidate successful at the entrance examination will be appointed as Acting Surgeon-Lieutenant in the Royal Navy and will be required to pass through such courses of instruction as the Admiralty may decide. At the end of the courses the acting surgeon-lieutenant will be examined and after he has passed will be given a commission as Surgeon-Lieutenant in the Royal Navy. The commission will date from the day of passing the entrance examination. An acting surgeon-lieutenant who fails to qualify in the above examination (i.e., who fails to get 50 per cent. of marks in each subject of the Greenwich and Haslar courses) will be allowed a second trial at the next examination, the period between the two examinations not being counted as service for either promotion, withdrawal with gratuity, or retirement after 20 years' service, and should he qualify he will be placed at the bottom of his list; should he again fail his appointment will not be confirmed and he will be required to withdraw.

A gold medal, a silver medal, and three navy regulation pocket cases will be awarded as prizes in connexion with these examinations, and the gold medalist will have a distinguishing mark after his name in the Navy List, provided he obtains 75 per cent. of the aggregate maximum.

Surgeon-Lieutenants on entry are only required to provide themselves with a regulation pocket case of instruments. Acting Surgeon-Lieutenants need only provide themselves with undress and mess uniforms.

A candidate, who at the time of passing the examination for entry holds or is about to hold an appointment as Resident Medical or Surgical Officer in a recognised civil hospital, may be allowed to serve in such civil appointment, provided that the period of such service after the date of entry into the Royal Navy does not exceed one year. Pay from Naval funds will be withheld from officers while thus serving, but the time concerned will reckon for increase of full and half pay while on the active list, and retired pay or gratuity on retirement or withdrawal; except that no officer will be allowed to retire on a gratuity until he has completed four years' service, exclusive of the time spent as Resident Medical or Surgical Officer. The eligibility of this appointment to count for time will be decided by the Medical Director-General.

The seniority of Surgeon-Lieutenants on entry will be determined by the sum total of the marks they obtain at the London examination and those at the conclusion of their probationary period as Acting Surgeon-Lieutenant. Their names will then be placed in the official navy list. Candidates who hold, or are about to hold, a post as resident medical or surgical officer to a recognised civil hospital will retain the position in the list which they obtained on entry, and when their period of service as resident officer is over they will join the next Acting Surgeon-Lieutenant's course and will be required to obtain qualifying marks. Surgeon-Lieutenants entered without competition will take seniority next after the last Surgeon-Lieutenant entered at the same time by competition.

A Naval Medical School has been established at the Royal Naval College, Greenwich. As the nucleus of an Instructional Staff two Surgeon-Commanders fill the posts of Professor of Bacteriology and Clinical Pathology and Professor of Hygiene. The course of instruction for Acting Surgeon-Lieutenants is six months in duration, two of which are passed at Greenwich in the study of Tropical Medicine, Bacteriology, Pathology, and Hygiene; and the remaining four at Haslar in the study of Naval Hygiene, Recruiting, Physical Training, Diving, Submarine Work, Radiography, Anaesthetics, Dentistry, &c. A Surgeon-Commander superintends these studies at Haslar and fills the post of Lecturer on Naval Hygiene. At the conclusion of the six months' course an examination is carried out as above mentioned.

#### Post-Graduate Instruction and Examination for the Rank of Surgeon-Lieutenant-Commander.

The post-graduate instruction of Naval Medical Officers consists of two courses: (1) A five months' course before promotion to Surgeon-Lieutenant-Commander; (2) a second course of three months for officers of not less than 14 years' seniority. The first course is compulsory for all Surgeon-Lieutenants, and is followed by examination before the Medical Examining Board in London, in order to qualify for promotion to Surgeon-Lieutenant-Commander. The course is to be taken when the surgeon has between three and five years' seniority, as near the latter date as practicable. These courses take place twice a year. There are six compulsory subjects: Clinical Medicine and Surgery, Operative Surgery, Practical Anaesthetics, Ophthalmology, Clinical Pathology, and Hygiene; and two optional subjects: Diseases of the Throat, Nose, and Ear, and Skiagraphy. A Surgeon-Lieutenant who fails to obtain a pass will be allowed a second trial; if again unsuccessful, he will be compulsorily retired with such gratuity as the Admiralty may see fit to grant.

Instruction in clinical pathology and hygiene, and skiagraphy is given at the Naval Medical School; the other subjects are studied at civil hospitals in London, as may be arranged by the Medical Director-General. The Surgeon-Lieutenants going through the course are accommodated at the Royal Naval College, Greenwich, under the general control of the President; their instruction being supervised by the Professor of Hygiene.

The second course is not compulsory, but is designed to afford senior officers an opportunity for refreshing their knowledge of surgery and medicine, and making themselves familiar with modern advances. There will not be any fixed syllabus, but arrangements will be made to meet individual requirements. The officers attending the course will also be accommodated at Greenwich.

Voluntary classes for instruction of about six weeks' duration are held at the Naval Hospitals at the three home ports (Chatham, Haslar, Plymouth) for the benefit of medical officers of ships and establishments at these ports, to whom every facility will be afforded for the study and practice of bacteriology, clinical pathology, skiagraphy, &c., in the hospital laboratories, a report being forwarded to the Admiralty at the close of each course.

#### Promotion to Surgeon-Lieutenant-Commander.

(a) Rank as Surgeon-Lieutenant-Commander will be granted, subject to their Lordships' approval, to Surgeon-Lieutenants at the expiration of

<sup>1</sup> If any doubt should arise on this question the burden of clear proof that he is qualified will rest upon the candidate himself.

six years from the date of entry, provided they are recommended by the Medical Director General, have served at sea for three years, and have passed the qualifying examination for this rank. (b) Special promotions will be made at their Lordships' discretion to the rank of Surgeon Lieutenant-Commander in cases of distinguished service or conspicuous professional merit. Such promotions will be exceptional and not exceed the rate of one a year. The total number at any one time of Surgeon Lieutenant-Commanders holding that rank by such special promotions will not exceed eight. These limitations do not apply to promotions for gallantry in action.

(c) *Accelerated Promotion.*—Certificates will be granted at the qualifying examination for Surgeon Lieutenant-Commander as follows:—50 per cent. of marks for a pass; 75 per cent. for a first class, and 85 per cent. for a special certificate. An officer obtaining a first class is eligible for an advance of 12 months' seniority, and one obtaining a special certificate for 18 months' seniority; this acceleration will not be granted on examination results alone, and an officer must also be recommended as deserving of advancement. The amount of seniority allowed may be reduced, if considered advisable by the Director General; and if a Surgeon-Lieutenant fails to pass at the first attempt, the results of a second successful trial will not count towards accelerated promotion.

#### *Promotion to Surgeon-Commander.*

(a) Subject to the approval of the Lords Commissioners of the Admiralty rank as Surgeon-Commander will be granted to Surgeon Lieutenant-Commander at the expiration of six years from the date of promotion to Surgeon Lieutenant-Commander, provided they are recommended by the Medical Director General, have served in that rank at sea for three years, and have not declined service except for reasons which in the opinion of the Lords Commissioners of the Admiralty are satisfactory. (b) Special promotions from the rank of Surgeon Lieutenant-Commander to that of Surgeon-Commander will be made at their Lordships' discretion in cases of distinguished service or conspicuous professional merit. Such promotions will be exceptional and will not exceed the rate of one in two years; the total number at any one time of Surgeon-Commanders holding that rank by such special promotions will not exceed six; these limitations do not apply to promotion for gallantry in action.

Promotions to Surgeon Rear-Admiral and Surgeon-Captain will be made strictly by selection, and will be confined to officers who have proved themselves to be fitted, both professionally and as administrators, for these ranks. For advancement to Surgeon-Captain two years' sea service in the rank of Surgeon-Commander will be required, or five years' combined service at sea in the ranks of Surgeon-Commander and Surgeon Lieutenant-Commander.

#### *Miscellaneous.*

The special attention of candidates is directed to the following rules under which officers are allowed to withdraw from the service after four years' full pay service in the Royal Navy, with the advantage of joining the Reserve of Naval Medical Officers:—

After four years' service in the Royal Navy, an officer, if he wishes, may pass from active service to the Reserve of Naval Medical Officers, when he will reap the following advantages:—

- (1) He will be granted a gratuity of £500 on passing into the Reserve.
- (2) His name will be retained in the Navy List; he will retain his naval rank and be entitled to wear his naval uniform under the regulations applying to officers on the retired and reserved lists of His Majesty's Navy.
- (3) If he agree to remain in the Reserve for four years he will receive a retaining fee of £25 per annum. If at the expiration of this period he agree to remain in the Reserve for a further period of four years he will continue to receive the same retaining fee.

Should an officer prefer it, however, he may simply enter the Reserve for a period not exceeding eight years, with power to give six months' notice of his intention to resign his position at any time (in which case he will receive no retaining fee). He may also adopt this method of Reserve service after the expiration of four years served under the conditions referred to in (3), by renouncing his retaining fee for his last four years' service in the Reserve.

No officer will be allowed to remain in the Reserve for a longer period than eight years. Whilst belonging to the Reserve, officers must report any change of address to the Secretary of the Admiralty.

Any officers who from residence abroad, physical disability, or for other reason may be considered by the Admiralty to be not immediately available for service, if required, will be liable to removal from the Reserve and forfeiture of retainer.

Officers of the Reserve will be liable to serve in the Royal Navy in time of war or emergency. When called up for such service they will receive the rate of pay—viz., 23s. a day and allowances—to which they would have been entitled after four years' service on the Active List, and an outfit allowance of £20.

A limited number of active or retired medical officers are appointed Honorary Physician or Honorary Surgeon to the King. There are three good service pensions of £100 a year; two Greenwich Hospital pensions of £100 a year; and 13 of £50 a year awarded to Naval Medical Officers. The Gilbert Blane gold medal is awarded every year to the medical officer who obtains the highest aggregate marks at the promotion examination to Surgeon Lieutenant-Commander, held at the Royal Naval Medical School, Greenwich. Once in every five years a gold medal and £100, the Chadwick Naval or Military Prize, is presented to a naval or military medical officer who has specially assisted in promoting the health of the men in the Navy or Army.

A special cabin will be appropriated to the Surgeon-Commander or Surgeon Lieutenant-Commander, or the Surgeon-Lieutenant in charge of the medical duties in each ship. Medical officers not in charge will select their cabins, according to their rank and relative seniority, with other ward room officers.

Relative rank is accorded to medical officers as laid down in the King's Regulations and Admiralty Instructions.

Temporary Surgeon Lieutenants transferring to the permanent Service will be allowed to count seniority from date of original entry if their application to transfer is approved by the Board of Admiralty.

#### *Retired Pay.*

Surgeon Rear-Admiral, £900; service, 27 years. Addition for each additional year or fraction for each year short, £22.

Surgeon-Captains retire at the age of 55, maximum retired pay, £900.

Surgeon-Commanders retire at 50, maximum retired pay £600. Lieutenant-Commanders and Lieutenants retire at age of 45, maximum retired pay £450.

#### *Widow's Pension.*

Widows' pensions and compassionate allowances for children are given under the conditions as specified in the King's Regulations and Admiralty Instructions.

When an officer retires on a gratuity or withdraws on a gratuity his widow and children will have no claim to pension or compassionate allowance.

The fact of an officer retiring on pension does not deprive the widow or children of any claim to pension if they are so entitled at the time of his retiring.

Officers serving in the Reserve, who during re-employment are injured on duty or lose their lives from causes attributable to the Service, come under the same regulations as regards compensation for themselves or pensions and compassionate allowances for their widows and children as officers of the same rank on the permanent Active List.

#### THE PAY OF NAVAL MEDICAL OFFICERS.

The following improvements in the rates of full, half, and retired pay of naval officers have been approved by the Government after consideration of the report of the Board of Admiralty upon the recommendations of the subcommittee of Admiral Jerram's Committee, presided over by Rear-Admiral Halsey:—

#### *Full Pay.*

The new rates of pay will apply to officers of the Royal Navy and Royal Naval Volunteer Reserve.

Rank.	Before Feb. 1st.	Total Pay plus Bonus Feb. 1st.	New Rate.
	£ s. d.	£ s. d.	£ s. d.
Surgeon-Lt.—On entry ...	0 14 0	0 18 6	1 4 0

After 3 years ...			1 6 6
Surgeon Lt.-Cdr. (D).—			
On promotion ...			1 12 6
After 3 years ...			1 14 6
After 6 years ...			1 16 6

A Dental Surgeon who is also qualified medically to receive pay on the Medical Officers' scale.

#### *Specialist Allowances.*

Specialist allowances to officers specialised in professional subjects as indicated below. If a Surgeon-Commander is appointed solely for specialist duties he will receive pay as a Surgeon-Commander only. These allowances will not be paid after promotion to Surgeon-Captain, 2s. 6d. Anaesthetists not exceeding six allowances. Ophthalmic not exceeding 13 allowances. Ear and Throat not exceeding 13 allowances. Genito-urinary and Venereal not exceeding six allowances. Physical Training not exceeding six allowances.

#### *Promotion: New Scheme.*

The following alterations are made in the rules regarding promotion:—Medical Officers: (a) Surgeon-Lieutenants will be eligible for promotion after six years, instead of eight as at present, the promotion of those on the list on July 1st, 1919, being antedated as necessary. (b) Surgeon Lieutenant-Commanders will be eligible for promotion to Surgeon-Commander after six years, instead of eight as at present, those on the list on July 1st, 1919, being given two years' seniority. Instructions will be issued to the Fleet as regards the seniority of those Surgeon Lieutenant-Commanders now due for promotion owing to the double acceleration. (c) Surgeon-Commanders on the list on July 1st, 1919, will be given two years' seniority.

#### *Retirement.*

The following alterations in the regulations for retirement will be introduced:—Medical Officers: (a) Compulsory. Surgeon Rear-Admirals in future to be invariably retired at 60, the power of retention to the age of 62 in special cases being abolished. Surgeon-Captains to retire at 55. Surgeon-Commanders to retire at 50. Surgeon Lieutenant-

Commanders to retire at 45. (b) Optional retirement at 40 to be allowed for all ranks at Admiralty discretion. The new ages for compulsory retirement will be worked down to in five years, beginning with January 1st, 1920.

#### Miscellaneous.

*Medical and Dental Attendance.*—Officers on consolidated salary will in future be allowed the benefits of medical and dental attendance under the rules applicable to the Service generally.

*Increase in Higher Ranks of Certain Branches.*—Proposals are under consideration to increase the number in the higher ranks of the Medical Branch.

*Dental Surgeons.*—A branch of Dental Surgeons will be permanently instituted, with pay as shown in Appendix 1. Surgeon-Lieutenants (D) will rank with Surgeon-Lieutenants, and will be eligible for promotion to Surgeon Lieutenant-Commander (D) on attaining six years' seniority. No higher rank than that of Lieutenant-Commander will obtain in this branch. These officers will otherwise conform to the regulations applicable to officers of the Medical Branch. Further instructions will be issued as to the transfer of existing officers to the New Branch.

### ARMY MEDICAL SERVICE.

There has come into existence an alteration in the conditions of service in the Royal Army Medical Corps which constitutes the greatest reform that has taken place in that service for a generation. Moreover, it is a reform of promise as well as of performance. Directorates in Pathology and in Hygiene have now been created within the Army Medical Department, the scheme permitting for specially selected men to rise through all ranks of the Army to Major-General on the strength of their scientific work. Hitherto, a few notable men being excepted, the custom in the R.A.M.C. has been that whatever a man's qualifications, tastes, or abilities, he must, at any rate on attaining the rank of colonel, be prepared to go off into administrative work and leave his scientific duties to his juniors. If he preferred to remain working in bacteriology, in preventive medicine and hygiene, or in tropical diseases, for example, he could do so, but at the risk of losing appointments carrying temporarily higher rank and increased pay. Always young men were being taught, and well taught, how to become the scientific branch of their Corps, and exactly as they had found their *métier*, precisely as they had become valuable advisers of officers, men, the Army, and indeed the nation, they were asked to choose between sacrifice of their scientific work or a career of superintending other people, of giving orders, of supervising hospitals and military establishments generally—in short, a career of what is called administration. How could the younger men be expected to preserve their interest in their scientific studies if such was the outcome? And how could their seniors be expected to remain in touch with the scientific developments in whose working out they no longer had any personal share? This now has all been changed, largely owing to the pertinacious, skilful, and sympathetic work of Sir John Goodwin, Director-General of the R.A.M.C., who has for over a year been preparing his scheme of reform with the assistance of the two principal exponents of scientific work with the Corps, Sir William Leishman and Sir William Horrocks. It is certain that the possibility, and for good workers the probability, of attaining to positions of proper trust and emolument by scientific work will much improve recruiting among the officers of the R.A.M.C.—that will be the immediate outcome of the new scheme; but there will almost certainly follow similar arrangements by which special medical service generally will receive higher consideration in the Corps. Not only is there in the work of the Army Medical Department scope for original labour and research in tropical disease, in preventive medicine, and in bacteriology, but a vast clinical field is also open to the specialist in medicine, surgery, venereal disease, and ophthalmology. Further developments will shortly follow, as well as properly increased rates of pay. These we hoped to have been able to publish this week, but they are not yet made formally available.

#### REGULATIONS.

Following are the Regulations for admission to the Royal Army Medical Corps (issued with Army Orders dated Jan. 1st, 1912).

A candidate for a commission in the Royal Army Medical Corps must be 21 years and not over 28 years of age at the date of the commencement of the entrance examination, and must be unmarried. He must, at the time of his appointment, be registered under the Medical Acts in force in the United Kingdom. A candidate must complete the subjoined form of application and declaration and submit it, together with an extract from the register of his birth, and his medical registration certificate, to the Secretary, War Office, as early as possible before the date on which the entries are closed.

#### APPLICATION OF A CANDIDATE FOR A COMMISSION IN THE ROYAL ARMY MEDICAL CORPS.

(A Candidate will not be permitted to compete oftener than twice.)

1. Name in full.
2. Address.
3. Date of birth.
4. Nature and date of examination qualifying for registration.
5. Date of registration as a medical student.
6. Dates of passing medical examinations—First, Second, Final.
7. Qualifications. (Medical Registration Certificate, or, if not registered, Diplomas to be furnished.)
8. Academic and other distinctions.
9. Medical school or schools in which the candidate pursued his course as a medical student, and name or names of the deans or other responsible authorities.
10. Particulars of any commission or appointment held in the public services, including service in the Officers Training Corps.
11. Date of examination at which the candidate proposes to present himself.

#### Declaration.

(N.B.—A mis-statement by the candidate will invalidate any subsequent appointment and cause forfeiture of all privileges for services rendered.)

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief and further:—

1. That I am a British subject of unmixed European blood.
2. That I am not, as far as I know, at present suffering from any mental or bodily infirmity, or physical imperfection or disability that is likely to preclude me from efficiently discharging the duties of an officer in any climate.
3. That I will fully reveal to the Medical Board, when physically examined, all circumstances within my knowledge that concern my health.

A candidate will not be permitted to compete oftener than twice.

The Army Council reserves the right of rejecting any candidate who may show a deficiency in his general education.

An entrance fee of £1 is required from each candidate admitted to the examination.

Candidates who have served in the Officers Training Corps will be credited at the entrance examination with additional marks as follows: those having Certificate A will receive 1 per cent., and those having B 2 per cent. of the total. Service marks are also credited to a candidate who has been employed as an officer in consequence of a national emergency, the number of marks depending on the period of employment and the circumstances of the case.

A candidate successful at the entrance examination will be appointed a Lieutenant on probation and will be required to pass through courses of instruction at the Royal Army Medical College, London, and at the Royal Army Medical Corps School of Instruction, Aldershot, and, after passing the examinations in the subjects taught and satisfying the Director-General that he possesses the necessary skill, knowledge, and character for permanent appointment to the Royal Army Medical Corps, his commission as Lieutenant will be confirmed. The commission will bear the date of passing the entrance examination. A Lieutenant who, at the time of passing the examination for admission to the Royal Army Medical Corps, holds, or is about to hold, a resident appointment in a recognised civil hospital, may be seconded for the period, not exceeding one year, of his appointment; he will not receive army pay, but his service will reckon towards pay, promotion, and retirement; he will retain the seniority obtained at the entrance examination.

The precedence of Lieutenants among each other will be in order of merit as determined by the combined results of the entrance examination and the examinations undergone while on probation, except that the position on the list of a Lieutenant on probation, seconded to hold a resident appointment in a recognised civil hospital will be determined by the place he has gained at the entrance examination. He will be required, at the conclusion of his hospital appointment, to attend the courses of instruction at the Royal Army Medical College and at Aldershot; but the subsequent examinations will be of a qualifying character and will not influence his position on the seniority list of the Corps.

Lieutenants when appointed on probation will receive instructions as to the provision of uniform.

On completion of his probationary training an officer is posted for duty to one of the military hospitals: at home, his wishes being met as far as possible in regard to the command to which he is posted.

### INDIAN MEDICAL SERVICE.

#### REGULATIONS.

Following are the Regulations for the examination of candidates for admission to the Indian Medical Service. The grades of officers in the Indian Medical Service are the same as those of the Army Medical Service and Royal Army Medical Corps. The Director-General will rank either as Major-General or Lieutenant-General as may be decided in each case by the Secretary of State for India in Council.

Candidates must be natural-born subjects of His Majesty, of European or East Indian descent, of sound bodily health, and in the opinion of the Secretary of State for India in Council in all respects suitable to hold commissions in the Indian Medical Service. They may be married or unmarried. They must possess under the Medical Acts a qualification registrable in Great Britain and Ireland. No candidate will be permitted to compete more than three times. Examinations for admission to the service are held twice in the year, usually in January and July. Candidates for the January examination must be between 21 and 28 years of age on Feb. 1st, and those for the July examination must be between 21 and 28 on August 1st. The exact date of each examination and the number of appointments, together with the latest date at which applications will be received, will be notified in THE LANCET.

They must subscribe and send in to the Military Secretary, India Office, London, S.W., so as to reach that address by the date fixed in the advertisement of the examination, a declaration according to the annexed form, which is procurable from the Military Secretary.

*Declaration and Schedule of Qualifications to be Filled up by Candidates.*

I, ....., a candidate for employment in His Majesty's Indian Medical Service, do hereby attest my readiness to engage for that service, and to proceed on duty immediately on being gazetted.

I declare that I labour under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer.

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief.

I enclose, in accordance with Paragraph 4 of the Regulations, (a) proof of age; (b) two certificates of character; (c) certificate of having attended a course of ophthalmic instruction, showing that the course included instruction in errors of refraction; (d) evidence of a registrable qualification; (e) in case of natives of India or others educated in that country only, a certificate from the Director-General, Indian Medical Service.

Signature ....., 19 .....

Date ....., 19 .....

1. Name in full.
2. Address. (Any alteration to be notified to the Military Secretary, India Office, London, S.W.)
3. Date of birth. (This must be supported by a certificate or statutory declaration. See Paragraph 4 of the Regulations.)
4. Profession or occupation of father, and whether, at the time of candidate's birth, his father was a British subject of European or East Indian descent.
5. Statement as to whether the candidate is married or single.
6. Colleges and Medical Schools at which the candidate has received his medical education.
7. Medical School in which the candidate completed his course as a medical student, and name of the Dean or other responsible authority.
8. Degrees of B.A. or M.A.; details as to any prizes, university honours, &c.
9. Registrable qualifications.
10. Date of examination at which the candidate proposes to present himself.
11. Date of any previous occasions on which the candidate may have presented himself for examination for admission to the Indian Medical Service, or other examination for the Public Services.
12. Particulars of any commission or appointment held in the Public Services.

The declaration must be accompanied by the following documents:—  
a. Proof of age either by Registrar-General's certificate, or, where such certificate is unattainable, by the candidate's own statutory declaration, form for which can be obtained at the India Office, supported, if required by the Secretary of State, by such evidence as he may consider satisfactory. A certificate of baptism which does not afford proof of age will be useless. In the case of natives of India and Tamils of Ceylon it will be necessary for a candidate to obtain a certificate of age and nationality in the form laid down by the Government of India which is obtainable from the Director-General of the Indian Medical Service, Simla. A candidate of East Indian descent, not born in British India, must produce a certificate of age and nationality from the Government of the country where he was born, showing that he is the son or grandson of a person born in British India. b. A recommendation and certificate of moral character from two responsible persons—not members of his own family—to the effect that he is of regular and steady habits and likely in every respect to prove creditable to the service if admitted. c. A certificate of having attended a course of instruction for not less than three months at an ophthalmic hospital or the ophthalmic department of a general hospital, which course shall include instruction in the errors of refraction. d. Some evidence of having obtained a registrable qualification. e. Any European educated in India and every native of that country, whether born or medically educated in India or not, will be required to produce a certificate signed by the Director-General, Indian Medical Service, that he is a suitable person to hold a commission in the Indian Medical Service. A candidate should apply to the Director-General, Indian Medical Service, for the necessary certificate at least three months before the date on which the declaration is to be submitted according to the advertisement of the examination. This rule also applies to Tamils of Ceylon.

The Secretary of State for India reserves the right of deciding whether the candidate may be allowed to compete for a commission in His Majesty's Indian Medical Service.

The physical fitness of each candidate will be determined by a Board of Medical Officers who are required to certify that his vision is sufficiently good to enable him to pass the regulation tests (see under Army Medical Service). Every candidate must also be free from all organic disease and from constitutional weakness or other disability likely to unfit him for military service in India. Candidates will be required to pay a fee of £1 before being examined by the Medical Board. No candidate will be permitted to compete more than three times. More detailed regulations as to the physical requirements can be obtained on application to the India Office.

Candidates for the Indian Medical Service may, if they like, undergo a preliminary examination by the Medical Board which meets at the India Office every Tuesday by applying to the Under Secretary of State, India Office, enclosing a fee of two guineas, and stating the particular appointment which the candidate desires to obtain. They must pay their own travelling expenses. The decision must be understood, however, not to be final. It may be reversed in either direction by the Examining Medical Board immediately prior to the Professional Examination.

On proving possession of the foregoing qualifications the candidate will be examined by the Examining Board in the following subjects and the highest number of marks attainable will be distributed as follows:—

	Marks.
1. Medicine, including therapeutics...	1200
2. Surgery, including diseases of the eye	1200
3. Applied anatomy and physiology...	600
4. Pathology and bacteriology	900
5. Midwifery and diseases of women and children	600
6. Materia medica, pharmacology, and toxicology	600

The examination in medicine and surgery will be in part practical and will include operations on the dead body, the application

of surgical apparatus, and the examination of medical and surgical patients at the bedside. No syllabus is issued in the subjects of the examination, but it will be conducted so as to test the general knowledge of the candidate in all subjects. No candidate shall be considered eligible who shall not have obtained at least one-third of the marks obtainable in each of the above subjects and one-half of the aggregate marks for all the subjects.

After passing this examination the successful candidates will be commissioned as lieutenants-on-probation, and will be granted about a month's leave. They will then be required to attend two successive courses of two months each at the Royal Army Medical College, Millbank, and at Aldershot. The candidate's commission as a lieutenant-on-probation will bear the date on which the result of the entrance examination is announced, but his rank as lieutenant will not be confirmed until he has passed the final examination, held at the conclusion of his period of instruction.

The course at the Royal Army Medical College will be in (1) hygiene, (2) military and tropical medicine, (3) military surgery, (4) pathology of diseases and injuries incidental to military and tropical service; and (5) military medical administration.

The course at Aldershot will include instruction in (1) internal economy, (2) Army Service Corps subjects, (3) hospital administration, (4) stretcher and ambulance drill, and (5) equitation.

Lieutenants-on-probation will receive an allowance of 14s. per diem, and during the period of instruction they will be provided with quarters (where quarters are not provided they will obtain the usual allowances of a subaltern in lieu thereof), to cover all costs of maintenance, and they will be required to provide themselves with uniform; a detailed list of the uniform and articles required will be sent to each successful candidate.

A lieutenant-on-probation who is granted sick leave before the completion of his course of instruction and final admission to the service will receive pay at the rate of 10s. 6d. a day for the period of his sick leave.

Candidates will be required to conform to such rules of discipline as may from time to time be laid down.

At the conclusion of each course the candidate will be required to pass an examination on the subjects taught, and in order to qualify must obtain 50 per cent. of the total marks. If he fails to qualify in either of these examinations he will be liable to removal from the service, but if specially recommended he may be allowed to undergo the course or courses again under certain restrictions as to pay and position.

Officers appointed to the Indian Medical Service will be placed on one list, their position on it being determined by the combined results of the preliminary and final examinations. They will be liable for military employment in any part of India, but in view of future transfers to civil employment, they will stand posted to one of the following civil areas:—(1) Madras and Burma; (2) Bombay with Aden; (3) Upper Provinces—i.e., United Provinces, Punjab, and Central Provinces; and (4) Lower Provinces—i.e., Bengal, Bihar, Orissa, and Assam. The allocation of officers to these areas of employment will be determined upon a consideration of all the circumstances, including, as far as possible, the candidate's own wishes. Officers transferred to civil employment, though ordinarily employed within the area to which they may have been assigned, will remain liable to employment elsewhere according to the exigencies of the service.

A lieutenant who, within a reasonable period before the date at which he would otherwise sail for India, furnishes proof of his election to a resident appointment (or to a preliminary appointment leading in due course to a resident one) at a recognised civil hospital, may be seconded for a period not exceeding one year from the date on which he takes up such appointment, provided that he joins it within three months of passing his final examination, and that he holds himself in readiness to sail for India within 14 days of the termination of the appointment. While seconded he will receive no pay from Indian funds, but his service towards promotion, increase of pay, and pension will reckon from the date borne on his commission. In special cases permission may be granted to lieutenants to delay their departure for India, in order to sit for some further medical examination. Lieutenants remaining in England under such circumstances will receive no pay for any period beyond two months from the date of termination of the course of instruction, unless the period elapsing before the day on which the majority of the lieutenants of the same seniority sail to India exceeds two months, in which case lieutenants allowed to remain in England will receive pay up to that day. In such cases pay will recommence on the day of embarkation for India. All the provisions of this clause are subject to the general exigencies of the service. Before the commission of a lieutenant-on-probation is confirmed he must be registered under the Medical Acts in force at the time of his appointment. Candidates who have been specially employed in consequence of a national emergency, either as an officer, or in a position usually filled by an officer, will be allowed, under certain circumstances, to reckon such service towards pension.

**NEW RATES OF PAY.**

The new rates of pay in the Indian Medical Service, of which particulars follow, have been arrived at by adding approximately 33½ per cent. to that portion of the old rates of pay which represented military grade pay. The old rates are shown in the second column for comparison. The new rates are effective from Dec. 1st, 1918, and the necessary adjustments will be carried out as soon as possible.

**A.—Military Side.**

	(1) New rate.	(2) Old rate.*
	Rs. p.m.	Rs. p.m.
Lieutenants	550	(450)†
Captains	700	(550)
Captains (after 5 years' total service)	750	(600)
Captains (after 7 years' total service)	800	(650)
Captains (after 10 years' total service)	900	(700)
Majors	1000	(800)
Majors (after 3 years' service as such)	1150	(950)
Lieut.-Colonels	1550	(1250)
Lieut.-Colonels (of over 25 years' service)	1650	(1300)
Lieut.-Colonels (selected for increased pay)	1750	(1400)

\* Old rate for charge of a Regiment.

† In the case of a Lieutenant the rate for an officer in officiating charge only has been shown, as this is the most probable position of a Lieutenant.

These rates were previously announced in May, but at that time the rates for the civil side were not available. They are now republished with the civil rates in order that full information for the whole service may be available.

The new rates are consolidated and include charge pay for the command of station hospitals.

The following rates are those for certain of the higher military appointments:—

	(1) New rate. Rs. p.m.	(2) Old rate. Rs. p.m.
D.D.M.S. (if held by a Major-General) ... ..	2650	(2210)
D.D.M.S. and A.D.M.S. (if held by a Colonel) ...	2150	(1800)
A.D.M.S. of Adm. Inspector of Medical Services, Army Headquarters ... ..		
A.D.M.S. in the Field (when held by an officer below Colonel's rank) ... ..	1950	(1600)
Officer Commanding general hospital in the field of 500 beds ... ..		
A.D.M.S., Army Headquarters ... ..	1700	(1400)

B.—Civilian Side.

(1) The rates for certain of the superior appointments are as follows:—

	(1) New rate. Rs. p.m.	(2) Old rate. Rs. p.m.
Director-General ... ..	3500	3300
Deputy Director-General ... ..	2150	1500*
Assistant Director-General ... ..	1700	1400*
Surgeon-General, Bengal, Madras, and Bombay ... ..	3000	2500
Inspectors-General of Civil Hospitals in non-Presidency Provinces† ... ..	2600	2250
Sanitary Commissioner to Government of India ... ..	2300—2800	2000—2500
Sanitary Commissioner (for all provinces except Central Provinces and Assam) ...	1800—2100	1250—1800
Sanitary Commissioner, Central Provinces and Assam ... ..	1550—2050	
Inspectors-General of Prisons, Madras, Bengal, Burma, Bombay, and United Provinces ...	2100—2300	1500—2000
Inspectors-General of Prisons, Punjab, and Bihar and Orissa ... ..	2100	
Inspectors-General of Prisons, Central Provinces ... ..	1800	

\* Rates drawn by present incumbents.

† Corresponding to the appointments of Surgeon-General in the three Presidency Provinces.

(2) The distinction between 1st and 2nd class civil surgeoncies is abolished, and holders of these appointments will, in future, be paid at the new consolidated rates, given under A above, according to their military rank. This change results in increases varying according to rank from Rs. 200—400 per mensem.

‡ Assuming that a civil surgeoncy is not held by an officer of lower rank than a Captain.

(3) Holders of professorial and bacteriological appointments will, like civil surgeons, be paid at the new consolidated rates, given under A above, plus a special allowance of Rs. 250 per mensem. The resultant increase over the old rates varies from Rs. 150 per mensem in the case of junior Captains to Rs. 400 per mensem in the case of senior Lieutenant-Colonels.

(4) Holders of other special classes of appointments will receive the consolidated pay of rank, as under A above, plus special allowances of differing amounts—e.g., alienists and plague officers Rs. 200 per mensem, superintendents of first-class jails Rs. 150 per mensem, personal assistants to Surgeons-General Rs. 100 per mensem, superintendents to second-class jails Rs. 50 per mensem.

The examples above are not exhaustive, but are given as illustrations of the manner in which the principle previously announced has been carried into effect.

ROYAL AIR FORCE MEDICAL SERVICE.

The Medical Service of the Royal Air Force has not yet been placed upon a permanent basis; the definite conditions of service are not therefore available for publication. It is understood, however, that the general organisation of the Service will be on the lines followed by the other branches of the Force, and that the establishment will consist partly of permanent and partly of temporary officers.

Temporary officers will be required to engage for a period of four years, and may be called upon to spend part of their service at overseas stations—chiefly in Egypt or India—and must be physically fit for service in all climates.

Unless taken in for some specific duty on account of special professional qualifications, medical officers will be required to pass the usual medical tests required of other officers of the flying service, and at the time of entry must sign a declaration that they are willing to fly when called upon to do so.

Vacancies in the establishment of permanent commissioned officers will be filled from the temporary list by selection. Those selected for permanent commissions will count the period of their temporary service towards eventual pension, the remainder will receive a gratuity on leaving the Service at the expiration of their contract.

There will be no competitive examination on entry; candidates must be under 28 years of age, be nominated by the Dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance.

Arrangements are being made to allow post-graduate courses after selection to permanent commission.

Officers engaged in research or pathological work will be promoted separately from the general roster.

Officers selected for the permanent service will normally be promoted to the rank of major after a fixed period of service, but officers specially selected on account of professional or administrative ability will become available for promotion to the rank of major at an earlier date.

Promotion to the higher ranks will be by selection only.

The rates of pay and pension are not yet finally fixed, but it is understood that in the junior ranks the rates will be rather higher than the corresponding rates in the R.A.M.C. to cover the flying risk.

THE COLONIAL MEDICAL SERVICE.

In the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; appointments in Egypt and the Soudan are regulated from the Foreign Office; in Aden and adjacent territories the appointments are under the control of the Government of Bombay; in Rhodesia the appointments are made by the British South Africa Company, London Wall Buildings, E.C.; in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E.C., for appointments; and those in Sarawak are in the hands of H. H. the Rajah.

But in addition to all these there are a large number of important posts under the patronage of the Secretary of State for the Colonies. These concern East Africa (the East Africa, Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates); Eastern (Ceylon, the Straits Settlements, and Federated Malay States, Hong-Kong, Weihaiwei, Mauritius, and Seychelles); West India (British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward I-lands, Barbados, British Honduras, and the Bahamas); Fiji and the Western Pacific, Cyprus, Malta, Gibraltar, St. Helena, Bermuda, and the Falkland Islands; and West Africa (Nigeria, the Gold Coast, Sierra Leone, and the Gambia). As a general rule, each Colony or Protectorate has its own public service distinct from that of every other, and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another; but there are two exceptions to this rule. The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, form one service, and in practice the medical services of the Straits Settlements and the Federated Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States, or *vice versa*. In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are almost always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. Appointments in Malta are all filled locally. Vacancies in the Hong-Kong Medical Department are generally filled by transfer from other Colonies. Medical appointments in the Bechuanaland Protectorate, Basutoland, and Swaziland are made only on the recommendation of the High Commissioner for South Africa, who usually appoints local candidates. In most cases the duties of a colonial medical officer are of a very general character, including medical, surgical and often public health work. It is only occasionally that a specialist is required. All applicants must be between the ages of 23 and 35, but in the case of East Africa, Uganda, Nyasaland, Somaliland, and Zanzibar preference will be given to candidates who are over 25 years of age, while in the case of Fiji and the Western Pacific preference will be given to candidates who are under 30. Candidates must be doubly qualified, and the choice will usually fall, other things being equal, on those who have held hospital appointments. Before being definitely appointed candidates will be medically examined by one of the consulting physicians of the Colonial Office: Sir J. Rose Bradford, K.C.M.G., 8, Manchester-square, London, W.; Sir J. Hawtrey Benson, 57, Fitzwilliam-square, Dublin; Lieutenant Colonel J. Arnott, I.M.S., 8, Rothesay-place, Edinburgh; and W. T. Prout, Esq., C.M.G., 14, Rodney-street, Liverpool.

*East African Protectorates.*—Medical Officers in the East Africa, Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates are appointed on probation in the first instance for three years, at the end

of which period their appointments are made permanent if their service has been satisfactory, but special arrangements are now in force in Uganda. The salary of a Medical Officer during probation is £400 per annum fixed, but as soon as he has been confirmed in the permanent appointment his salary rises by annual increments of £20 to £500 per annum, with duty allowance of £40 a year; and after six years' service, £525, rising by annual increments of £25 to £600 a year with duty allowance of £50 a year. There are 23 appointments of this nature in the East Africa Protectorate, 14 in Uganda, 11 in Nyasaland, 4 in Zanzibar, and 3 in Somaliland. In the East Africa Protectorate there are certain special appointments—viz., Deputy Principal Medical Officer (£750-25-850 and £75 duty allowance), Bacteriologist (£600-25-750, duty allowance £50), Assistant Bacteriologist (£500-25-600 duty allowance £50), two Senior Medical Officers (£500-25-750, duty allowance £60), Principal Sanitation Officer (£750-25-850 duty allowance £75), 13 Medical Officers of Health, graded as Medical Officers. In Uganda the post of a Deputy Principal Medical Officer is under consideration; there are two Senior Medical Officers, a Bacteriologist, and a Medical Sanitation Officer at £600-25-750, with duty allowance of £60, and a Medical Officer of Health on the same scale as a Medical Officer. In Zanzibar there is a Medical Officer of Health graded as a Senior Medical Officer, and an Assistant Medical Officer of Health graded as a Medical Officer, with allowances of £100 and £50 respectively, subject to their possessing the Diploma in Public Health. The salary attached to the appointment of Principal Medical Officer in the East Africa Protectorate and Uganda is £850 per annum, rising to £1000 per annum by annual increments of £50, and duty allowance £85; in Nyasaland £750-25-850 and duty allowance, £75; and in Zanzibar £600-25-750 and duty allowance, £60. The Head of the Medical Department in Somaliland is graded as a Senior Medical Officer. Medical Officers are permitted to take private practice on the understanding that they give precedence to their official duties.

**Straits Settlements.**—Medical Officers are appointed as House Surgeons or Assistant Health Officers at a salary of £350. After one year's satisfactory service House Surgeons are appointed Medical Officers with salary rising from £400 to £600. Above this class there are nine senior appointments carrying salaries ranging from £600 (rising to £720) to £750 (rising to £900). The Principal Civil Medical Officer receives £1050, rising to £1200. Duty allowances are attached to all appointments and free quarters, or an additional allowance in lieu thereof, are given to House Surgeons. The authorised establishment is at present 32 officers.

**Federated Malay States.**—Appointments are graded as follows:—Principal Medical Officer, £1050 to £1200; Senior Medical Officer, Perak, £750, rising to £900; Senior Medical Officer, Selangor, £800, rising to £1000; seven Medical Officers Grade I., £600, by £20 annually to £720; 18 Medical Officers, Grade II., £350, and after one year's satisfactory service £400, rising to £600, with free furnished quarters, without private practice. The Senior Medical Officers, in Perak and Selangor and the two Grade I. Medical Officers in charge of Negri Sembilan and Pahang are allowed consulting practice only. Other Medical Officers are prohibited from private practice except in very special cases where the Chief Secretary is satisfied that, owing to the absence of private practitioners, it is absolutely necessary to allow the Government Medical Officer to attend to private patients. The posts of Medical Officer, Grade II., in the Federated Malay States and the corresponding appointments in the Straits Settlements are filled by the promotion of officers who have entered the service as House Surgeons. A non-pensionable allowance, varying with the appointment, is attached to all medical posts in the Straits Settlements and Federated Malay States. In the case of House Surgeons the allowance is at the rate of £40 a year.

**Seychelles.**—There are four medical appointments. The Assistant Government Medical Officers receive Rs. 5000. The holders of these appointments have free quarters. Private practice is allowed.

**Wethaiwei.**—There are two non-pensionable Medical Officers on salaries £400-25-500, with free quarters.

**British Guiana.**—There are 35 appointments. Candidates must have held for at least six months a resident medical appointment in some public institution. Officers are appointed on two years' probation as assistant medical officers, and are paid a salary at the rate of £300 per annum, with quarters, without the right to private practice. The permanent staff, to which officers may be appointed at the expiration of the probationary period, includes the following appointments: Surgeon-General, £900, with travelling expenses and consulting practice; Bacteriologist and Pathologist, £300 to £600; 14 Medical Officers at £500 to £600; 17 Medical Officers at £300 to £500; and two at £300. Officers, on the completion of two years' service in the fixed £300 class, automatically rise to the £300-£400 class. Medical officers appointed to districts receive travelling allowances varying with the nature of the district. They are also allowed private practice. Medical Officers attached to public institutions are, in general, allowed free quarters, and receive a duty allowance. A deduction of 4 per cent. is made from their salaries for the payment of the premiums on an insurance of the officer's life for the benefit of the widow or orphans. The Governor has the power to appoint private practitioners on temporary agreements to perform in the duties of medical officers of districts.

**Trinidad and Tobago.**—In Trinidad and Tobago there are over 40 appointments. Officers are appointed in the first instance on two years' probation as supernumeraries and are eligible for appointment as Government Medical Officers at the end of this period. Applicants must be unmarried and must remain unmarried whilst supernumerary Medical Officers. Supernumeraries receive a salary of £250 per annum with furnished quarters, and are usually attached to the Government hospital. Government Medical Officers receive salary at the rate of £250 per annum with quinquennial increments of £50 accruing from the date of first appointment as supernumerary Medical Officers. Most are employed as District Medical Officers, with private practice, a residence or a rent allowance of £50, a horse allowance, except in one district, and in some cases other allowances for institution work. All officers are required to contribute 4 per cent. of their salaries towards the pensions of the widows and orphans of public officers.

**Windward Islands (Grenada, St. Lucia, St. Vincent).**—The 25 appointments are, with few exceptions, district appointments with the right to private practice attached; the salaries paid by Government

vary from £250 to £350, with allowances in certain cases. The Governor has the power to transfer a medical officer from one island to another at his discretion. The appointments are pensionable.

**Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).**—The 24 appointments are of the same nature as in the Windward Islands, but are not pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £250 or £300 according to station, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred to any medical district in the islands, and in certain districts he may be required to perform magisterial duties. The medical officers receive fees for successful vaccinations, post-mortem examinations attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also, as a rule, allowed private practice.

**British Honduras.**—There are seven medical appointments (besides the principal post of Colonial Surgeon) each carrying a salary of £1700 per annum. Unless they already possess a Diploma of Public Health, medical officers are liable to be required before they join the colony to undergo a course of instruction at a laboratory of public health or analogous institution. The dollar = about 4s. 2d.

**Fiji and the Western Pacific.**—In Fiji the Government Medical Officers receive a salary of £400, rising by annual increments of £25 to £500, with partly furnished quarters, or a house allowance of £50. In some districts a medical officer is also a magistrate with a combined salary of £500, rising to £600, with free quarters. They are allowed private practice, so far as is consistent with the proper discharge of their duty to the Government, but in most districts the private practice is very small. In districts where there is no private practice, an allowance of £50 a year is granted. They are required either to take charge of hospitals or of districts, at the discretion of the authorities. The posts are pensionable. There are at present 13 Medical Officers, three of whom are also Magistrates, in addition to a Chief Medical Officer (£700 a year, rising to £800), a Medical Officer of Health (£500, rising to £600), and a Senior Medical Officer (£450-£500). The medical services of Fiji and the Western Pacific are interchangeable. While serving in the Western Pacific Protectorates their duties may be of a quasi-magisterial nature, and they draw an extra non-pensionable allowance of £50 per annum.

**Cyprus.**—There is a Chief Medical Officer paid at the rate of £550 per annum, and three District Medical Officers paid at the rate of £340 per annum, all enjoying private practice (except the Chief Medical Officer, who is allowed consulting practice only) and receiving 2s. per diem forage allowance; these are the only medical appointments in the island which are open to English candidates.

**Gibraltar.**—There is a surgeon of the Colonial Hospital receiving £400 with fuel and light allowances, and private practice. He also receives £50 for medical examination of school children. There are also two Assistant Surgeons with a salary of £350 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

**St. Helena.**—The Colonial Surgeon at present receives £270 per annum £20 fees as Health Officer, and £27 horse allowance. Private practice is allowed. The Assistant Colonial Surgeon receives £350 a year and a horse, with forage allowance; but no private practice is allowed without special permission.

**Falkland Islands.**—There are two appointments. The Colonial Surgeon is paid at the rate of £350 per annum, with £25 as Health Officer. The Assistant Colonial Surgeon is paid at the rate of £400 per annum without quarters. Part of the salary is provided from private sources. Private practice is allowed to the Colonial Surgeon, and to a lesser extent to the Assistant Colonial Surgeon.

**Leave and Passages.**—In the East African Protectorates leave of absence on full salary is granted in the normal case after a tour of residential service (of not less than 20 nor more than 30 months) to an amount of five days for each completed month of residence (or 23 days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro. Officers serving in Uganda, Zanzibar, or in certain stations in the East Africa and Nyasaland Protectorates are allowed six or three days' leave respectively in respect of each month of service. In Somaliland special leave regulations exist which provide for an officer taking leave approximately every year. Free first-class passages are provided for the officer only. In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half pay may be granted on special grounds. If an officer on the occasion of his first leave is in receipt of a pensionable salary of less than £500 a year, he is granted a free return passage to the United Kingdom. In Hong-Kong leave of absence on half salary may be granted after 4½ years' service, and a portion of such leave may be commuted, if the Governor agrees, for half the amount on full pay. Leave of absence in excess of 10 months at a time will not be granted, but an extension may be allowed for ill-health or very urgent private affairs.

Subject to the necessities of the service, leave of absence on half salary may be granted to officers in other Colonies on the tropical Africa after a period of six years' resident service without any special grounds. Officers of the Fiji and Western Pacific service proposing to spend their leave in Europe may receive a grant in aid of passage expenses of £60. Leave may be given before the expiration of the due period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months in any two years. In the case of Fiji and the Western Pacific and the Falkland Islands 4½ months' leave may be granted in any three years.

On first appointment an officer whose salary and fees together do not exceed £500 a year will, except in the case of a few colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. This rule applies also to officers appointed to the Malay Peninsula and Hong-Kong. An officer taking leave out of the Colony has to provide his own passages.

<sup>1</sup> In the Straits Settlements and Federated Malay States all permanent Government servants are required to contribute 4 per cent. of their salaries towards the provision of pensions for the widows and orphans of public officers.

**Pensions.**—Officers on the pensionable establishment in the East African Protectorates are at liberty to retire on attaining the age of 50 years. Earlier retirement in the event of ill-health is also provided for. Pensions are computed on the scale of one-sixtieth of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement, but for purposes of calculating pensions two years' service is reckoned as service for three years. In most of the other Colonies an officer holding a pensionable appointment may be allowed to retire on ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For salary of the retiring officer's fixed appointments for three years prior to retirement it may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half pay as half service. In a few cases the retiring age is 60, and the pension after ten years' service is ten-sixtieths instead of fifteen.

#### West African Medical Staff.

The medical services of the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria—form one service under the above name. All the medical officers for the service are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. As in other Colonies, applicants must be between 23 and 35 years of age and possess a double qualification, but preference is given to those over 25. The higher grades are usually filled by promotion from the lower.

The grades and emoluments of officers of the staff are as follows:—The Director of the Medical and Sanitary Service in Nigeria receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year. Principal Medical Officer: The Principal Medical Officers receive salaries as follows: In the Gold Coast and the Southern Provinces of Nigeria £1200 a year, with a duty allowance at the rate of £240 a year. In Nigeria (Northern Provinces), £1100 a year, with a duty allowance at the rate of £220 a year. In Sierra Leone, £1000 a year, with a duty allowance at the rate of £200 a year. There is no Principal Medical Officer in the Gambia.

Deputy Principal Medical Officer: There are four appointments of this grade, two in the Southern Provinces of Nigeria and one each in the Northern Provinces and in the Gold Coast respectively. Salary at the rate of £900 a year, rising by annual increments of £25 to £1000 a year, is attached to these appointments, together with a duty allowance at the rate of £180 a year.

Senior Sanitary Officer: There are four appointments of this grade, two in Nigeria, one in the Gold Coast, and one in Sierra Leone. Salary at the rate of £900 a year, rising by annual increments of £25 to £1000 a year (in Sierra Leone to £950 only), is attached to these appointments, together with a duty allowance at the rate of £180 a year.

Provincial Medical Officer: There are seven appointments bearing this title (four in Nigeria, two in the Gold Coast, and one in Sierra Leone), with salary at the rate of £800 a year, rising by annual increments of £25 to £900 a year, and duty allowance at the rate of £160 a year.

Senior Medical Officer: There are 20 appointments of this grade, with salary at the rate of £600 a year, rising by annual increments of £25 to £750 a year, and a duty allowance at the rate of £120 a year. The Senior Medical Officer of the Gambia draws staff pay at the rate of £120 a year, in addition to duty pay, but is not allowed private practice.

Sanitary Officer: There are seven appointments of this grade, with salary at the rate of £700 a year, rising by annual increments of £25 to £800 a year, and a duty allowance at the rate of £140 a year.

Medical Officer: The salary attached to this grade is at the rate of £400 a year, rising by annual increments of £20 to £500 a year, with duty allowance at the rate of £80 a year. Medical Officers who have served for five years and are recommended for a higher rate of salary are required to take a special course of study for three months. If placed, on completing six years' service, on a scale of salary at the rate of £525 a year, rising by annual increments of £25 to £600 a year, with duty allowance at the rate of £100 a year. A Medical Officer who has served for three years on the maximum salary of this scale (£600) without obtaining promotion is eligible for the grant of further annual increments of £25 up to a total maximum salary of £750 a year.

Special appointments: The Director of the Medical Research Institute, Lagos, receives a salary of £600 a year, rising by annual increments of £25 to £800 a year, with a duty allowance of £120 a year. Salary year, is attached to abolition posts (those of Pathologists at Accra, Assistant at the Medical Research Institute, Lagos, and Medical Officers of Health at various places), irrespective of the seniority of the officer holding the appointment. In addition to the duty pay (£100 a year), the holder of the appointment draws half of the staff pay (£100 a year), and of absence, the remainder being drawn by his locum tenens.

**Leave and Passages.**—The ordinary tour of residential service is one year, followed by leave with full pay during the voyages to and from England, and for four or two months clear in England, according as the officer is returning for further service in West Africa or not. If an officer is detained beyond the year, additional leave is given with full pay for ten days in respect of each completed month beyond twelve, whether he is returning or not. If he is invalided before the end of the year, the leave with full pay is for the voyages and for ten or five days in respect of each completed month, according as he is returning or not, known as "ret. on leave," and any pay drawn in respect of such leave is liable to be refunded if he does not return. Leave may be extended on ill-health, or without pay on that or other grounds. Free passages are given to all officers who are granted leave, and free passages are also given on first appointment, subject to the officer signing an agreement under which he is liable to refund its cost if he relinquishes his appointment for any other reason than physical or mental infirmity, or is removed for misconduct, within three years from the date of his arrival in West Africa. Half pay is given during the voyage out on first appointment.

**Private Practice.**—All officers of the Staff except Principal Medical Officers, Deputy Principal Medical Officers, Provincial Medical Officers, Sanitary Officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that

it does not interfere with the efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at the majority of stations, and as a general rule, subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the staff.

**Pensions and Gratuities.**—These vary in accordance with the regulations of each Colony, but generally speaking an officer on attaining the age of 50 years, or after 15 years' service (of which at least 12 must have been residential) is qualified for a pension calculated at one-fortieth of the last annual salary for each year of service. If invalided after a minimum of seven years' service, he is qualified for a pension calculated at the same rate. If invalided before completing seven years' service he is qualified for a gratuity not exceeding three-quarters of a month's salary for each six months of service; provided that he has been confirmed in his appointment. For the purpose of calculating the amount of these pensions and gratuities, leave of absence without salary is not counted, while leave with half salary is counted at the rate of one month for every two months of such leave. An addition, representing the value of free quarters, is made to the officer's salary. This addition is as follows: To salaries of £400 a year, an addition of £40; to salaries above £400, but not exceeding £500, an addition of £50; to salaries above £500, but not exceeding £700, an addition of £60; to salaries above £700, but not exceeding £900, an addition of £70; to salaries exceeding £900, an addition of £80. In addition to the ordinary regulations, an officer of the West African Medical Staff enjoys the following special privilege: At the end of nine years (of which not less than six must have been residential) he will be permitted to retire with a gratuity of £1000, or at the end of 12 years (of which not less than eight must have been residential) with a gratuity of £1250. All claims to pensions are, however, forfeited on the receipt of such a gratuity. In the event of an officer dying in the service after completion of these gratuities, a sum equal to the gratuity in question will be paid to the credit of his estate. Officers are not allowed to take their wives out with them until they have acquired experience of the local conditions, and have obtained the sanction of the Governor. Passages for wives and children are not provided.

Candidates for medical appointments in West Africa are allowed to express a preference for any particular Colony or Protectorate, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary, to any other West African Colony or Protectorate at the discretion of the Secretary of State. Candidates who wish to be posted to the Northern Provinces of Nigeria should be able to ride. Candidates should on no account ultimately be transferred elsewhere, as the number of such transfers is exceedingly small. No applications for transfer can be entertained until an officer has served for five years in the West African Medical Staff, and officers desiring to be transferred must be prepared to find that medical salaries in other Colonies are lower than in West Africa. Only a small proportion of applicants succeed in obtaining a transfer. Officers who may be transferred to pensionable appointments under the Crown elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided they have been members of the Staff for at least 12 months.

**Instruction in Tropical Medicine.**—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for two or three months either at the London School of Tropical Medicine, Royal Victoria and Albert Hospital, E. (near Connaught Road Station), or at the Liverpool School of Tropical Medicine at the University of Liverpool. The cost of the tuition fees, board, and residence during such instruction, amounting to a maximum of £48 8s 10d., for three months, will be borne by the Government in the case of the London School; at Liverpool the cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £2 a week will be paid to them monthly in arrears for this purpose. A daily allowance of 5s. (but no salary) will be paid to each candidate, monthly in arrears, during the course and may be continued subsequently up to the date of embarkation. These payments must be refunded by the candidate if he declines to accept an appointment in any of the Colonies or Protectorates for which he may be selected, if he fails to obtain a certificate showing that he has satisfied the school authorities, or if he relinquishes the West African service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of the date of his arrival in West Africa. If at the end of the session there exist no vacancy in the staff to which a candidate can be appointed he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy.

**Course of study for higher scale of salary.**—The approved course of study is the three months' course of the West London Post-Graduate College or the London School of Clinical Medicine, Greenwich, in clinical medicine, clinical surgery, and pathology. Officers are allowed to substitute for this course either the course of study and examination for a recognised diploma or degree in public health, sanitary science, or State medicine; the course of study and examination for a further medical or surgical diploma or degree; or if the Governor, on the recommendation of the Principal Medical Officer, approves—a course of study in some special branch of medical or surgical practice (e.g., ophthalmology, dermatology, genito-urinary diseases), or an advanced course at the London or Liverpool School of Tropical Medicine. Whichever of these courses of study is selected, the necessary tuition and examination fees will be paid by the Colonial Government except in the event of an officer's deciding to enter for a further medical or surgical diploma or degree.

In conclusion it should be added that at the present time the age limits laid down for Colonial appointments are not always insisted upon, and that in a number of cases a temporary war bonus augments the salary.

<sup>2</sup> Except that the pension of an officer who has been promoted within three years of his retirement is calculated on the average of his salary for the last three years.

## DIPLOMAS IN STATE AND TROPICAL MEDICINE.

As usual we include in the Students' Number of THE LANCET an epitome of the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, State medicine, and tropical medicine. During the war some of this work has been suspended, for both teachers and taught being already registered medical men have been required in other spheres. But the public health of the country and of our colonial dependencies must be maintained, for this is one of our greatest guarantees of ultimate success in the struggle of endurance; and the machinery for the special education of public medical servants exists, as appears from what follows, and is ready to resume full activity at the earliest opportunity.

Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council from 1902 to 1911. Certain universities and corporations grant qualifications in Tropical Medicine which have not as yet been made registrable by statute.

*University of Oxford.*—An examination, conducted partly in writing, partly *visà voce*, and in each subject partly practical, is held in Michaelmas and Trinity Term in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £5 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise (a) a written paper of three hours in Chemistry and Physics; (b) a three hours' practical and *visà voce* examination in Chemistry and Physics.

The Second Part of the examination will consist of the following parts:—(a) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health); (b) a practical and *visà voce* examination in General Hygiene; (c) a written paper of three hours in Pathology and Bacteriology; and (d) a three hours' practical and *visà voce* examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce a certificate (1) of Laboratory Work in Chemistry as applied to Hygiene.

Candidates in Part II. will produce the following further certificates: (2) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration; (3) of having had Practical Instruction in Bacteriology, and the Pathology of the Diseases of Animals transmissible to Man; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration. The names of candidates must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford, to whom applications for any further information should be addressed.

*University of Cambridge.*—Two examinations in so much of State medicine as comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) general principles of hygiene; (2) bacteriology; (3) chemistry in Part I. of the examination; or (4) the second part of the examination, which has reference to State Medicine and to the applications of Pathology and Sanitary Science. Every

candidate will be required to pay a fee of £6 6s. before admission or readmission to either part of the examination, but candidates who have presented themselves before the year 1896 will be readmitted to either part on payment of a fee of £5 5s. Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provision (4), above mentioned.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University by Mr. J. E. Purvis on Hygiene, Chemistry, &c., and by Dr. Graham-Smith on Bacteriology. Professor G. H. F. Nuttall gives a course of lectures on Protozoal Diseases, and Dr. A. E. Shipley on Animal Parasites. For Part II Dr. A. J. Laird, the Medical Officer of Health for Cambridge, gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital and Dr. F. Robinson, the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology, Vital Statistics, &c. These courses are open to non-members of the University.

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Chemical Laboratory, Pembroke-street, Cambridge.

Two Examinations in Tropical Medicine and Hygiene are conducted yearly by the State Medicine Syndicate of the University of Cambridge. The examinations are held in Cambridge early in January and in the middle of August. Each examination will extend over four days.

Any person whose name is on the Medical Register is admissible as a candidate to the examination provided (I.) that a period of not less than 12 months have elapsed between his attainment of a registrable qualification and his admission to the examination; (II.) that he produce evidence, satisfactory to the Syndicate, that he has diligently studied Pathology (including parasitology and bacteriology) in relation to Tropical Diseases, Clinical Medicine, and Surgery at a Hospital for Tropical Diseases, and Hygiene and Methods of Sanitation applicable to Tropical Climates. As evidence of study and attainments a candidate may present to the Syndicate (1) any dissertation, memoir, or other record of work carried out by himself on a subject connected with Tropical Medicine or Hygiene; (2) any Certificate or Diploma in Public Health or Sanitary Science he may have obtained from a recognised Examining Body. Such evidence will be considered by the Syndicate in determining whether he is qualified for admission to the examination and by the examiners in determining whether, if admitted, he shall be included in the list of successful candidates.

The examination will be partly in writing, partly oral, and partly practical and clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment), and will have reference to the nature, incidence, prevention, and treatment of the epidemic and other diseases prevalent in tropical countries. Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma testifying to his knowledge and skill in tropical medicine and hygiene. The fee for the examination is £9 9s., and applications should be addressed to Dr. Graham-Smith, Medical Schools, Cambridge.

*University of London.*—Candidates for the M.D. degree may offer State medicine as a subject in which to graduate. They must send to the Academic Registrar with their forms of entry certificates (i.) of having, subsequently to having obtained a registrable qualification to practise Medicine, attended a course of practical instruction in a laboratory or laboratories, British or foreign, approved by the University, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught; such course to extend over a period of not less than six months and to consist of at least 240 hours, of which not more than one-half shall be devoted to practical chemistry. (ii.) Either of having, subsequently to having obtained a registrable qualification to practise Medicine, during six months (of which at least three months shall be distinct and separate from the above-mentioned period of laboratory instruction) been diligently engaged on not less than 60 working days in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a person recognised by the University as entitled to

grant certificates. Or of having held for a period of not less than three years an appointment as Medical Officer of Health of a Sanitary District within the British Dominions, and having a population of not less than 15,000. (iii.) Of having, subsequently to having obtained a registrable qualification to practise Medicine, attended at least twice weekly during a period of not less than three months a practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. In connexion with this degree the various metropolitan medical schools hold regular classes under teachers of Public Health and Sanitary Science, such instruction being also used to obtain the various diplomas of other Universities and of those Royal Corporations which grant them.

*University of Durham.*—Candidates for the degree of Bachelor of Hygiene (B.Hy.) must be at least 22 years of age, registered, and a graduate in Medicine of a recognised university. They must spend six months at Newcastle-upon-Tyne studying Comparative Pathology, Practical Bacteriology, Sanitary Chemistry, and Physics, and have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is £10 10s. and for the degree £6 6s. Candidates for the degree of Doctor of Hygiene (D.Hy.) must have acquired the degree of Bachelor of Hygiene, must for two years subsequently have been engaged in Public Health administration, or in research work relating to Public Health. The fee for the examination for the degree of D.Hy. is £5 and for the degree £10. The regulations for examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination is £10 10s. and for the diploma £3.

*Victoria University of Manchester.*—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5s., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3s. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin about the end of March and the middle of July in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

*University of Birmingham.*—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £5. Medical Officers of the Royal Navy who have attended courses in Hygienic Chemistry, Bacteriology, and Public Health at the Naval Medical School, Greenwich, will be admitted to the examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied

Chemistry and Bacteriology at the Staff College and pursued the further course of study approved by the General Medical Council.

*University of Liverpool.*—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The D.P.H. curriculum fees are: Chemistry, £5 5s.; Bacteriology, £5 5s.; Practical Sanitation, £15; Infectious Diseases, £3 3s. The courses may be taken out at any time, and students are allowed to work daily in the laboratories.

The University grants a Diploma in Tropical Medicine. Three courses of instruction are given every year. Two of these last for three full months—the Lent Course from Jan. 6th to April 5th and the Autumn Course from Sept. 15th to Dec. 13th. The Third Course, an Advanced Course, lasts one month, from June 1st to the 30th. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days and consists (1) of papers on Tropical Medicine, Tropical Pathology, and Tropical Sanitation and Entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. The fee for the full course of instruction is 13 guineas, with an extra charge of 10s. 6d. for the use of a microscope if required. The fee for the examination is 5 guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine. The new laboratories are completed and ready for occupation on the termination of the war.

*University of Leeds.*—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates may present themselves for Part I. (a), Part I. (b), and II. separately or at the same time, provided that no candidate be allowed to pass in Part II. unless he has already passed in Part I. Fees—The fee for each part is £5 5s., and for any subsequent examination in the same part £3 3s. Instruction in Sanitary Chemistry is given in the second and third terms and in Bacteriology during the first and second terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Dean of the Medical School.

*University of Bristol.*—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than 12 months' standing as such, and shall have passed the examination prescribed by regulation. The examination is divided into two parts. The subjects of the First Part are Chemistry as applied to Public Health and Pathology and Bacteriology. Candidates for the First Part shall, during six months after having obtained a registrable qualification, have received practical laboratory instruction in Hygienic Chemistry, in Bacteriology, and in the Pathology of the Diseases of Animals Transmissible to Man. The subjects of the Second Part are: Public Health and Epidemiology, Sanitary Law, Vital Statistics, and Sanitary Reporting.

For information as to Post graduate instruction apply to the Director of Post-graduate Studies, Professor Walker Hall.

*University of Edinburgh.*—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. A Diploma in Tropical Medicine and Hygiene is also granted. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after

graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3s. for the First and £3 3s. for the Second B.Sc. Examinations, and £10 10s. for the degree of D.Sc.

*University of Aberdeen.*—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom not less than 12 months after medical graduation. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University, together with having during six months (whereof three months must be distinct from the period of laboratory instruction) been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health administration under the medical officer of health of a county or large urban district. He must have regularly attended for three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. He must also have obtained practical instruction in the drawing and interpretation of plans. The diploma is conferred after an examination in Public Health held in March and July of each year. The fee is £5 5s.

*University of Dublin (Trinity College).*—The Diploma in Public Health is conferred, after examination, on the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least nine months before the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, four months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have studied practically outdoor sanitary work for six months under an approved officer of health, and must have spent three months' attendance at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus and a list of recognised laboratories may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

*National University of Ireland.*—At this University there is a Diploma in Public Health and a B.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climato-

logy, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (a) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (b) shall have pursued an approved course of study in the Faculty of Medicine; and (c) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

*University of Belfast.*—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held once yearly, Part I. in March and Part II. in June. The first part of the examination will have reference to the general principles of sanitary science, and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 1 guinea.

*Royal College of Physicians of London and the Royal College of Surgeons of England.*—The following are the regulations for obtaining the Diploma in Public Health: The examination consists of two parts. The first part of the examination takes place in January and July, and the second part in January and July. The fee for each part is £10 10s., except for those who are diplomates of the Royal Colleges, who pay £6 6s. for each part. A candidate intending to present himself must give 14 days' written notice to the Secretary, at the Examination Hall, Queen-square, London, W.C. 1. He will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification for at least 12 months; (2) of having attended thereafter practical instruction in a laboratory recognised by the Examining Board in England for at least 240 hours during a period of six months; and (3) of being at least 23 years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been diligently engaged in acquiring a practical knowledge of Public Health administration during six months under certain specified conditions; (2) of having attended during three months the clinical practice of a hospital for infectious diseases; and (3) of being at least 24 years of age.

*The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow.*—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Bacteriology in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer; and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (a) Laboratory Work (Chemistry and Bacteriology), (b) Physics and Meteorology; and the Second Examination embraces (a) Report on Premises visited, (b) Examination at Fever Hospital, (c) Examination at Public Abattoir, (d) Written and Oral Examinations on Epidemiology and Endemiology, (e) Vital Statistics and Sanitary Law, and (f) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected

candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and for Glasgow Mr. Walter Hurst, 242, St. Vincent-street.

*Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.*—Every candidate for the Diploma in Public Health must be a registered medical practitioner. He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months practically study outdoor sanitary work under a medical officer of health, and shall as an additional requirement attend a hospital for infectious diseases. Candidates are examined on four days, commencing on the first Monday of February, May, and November. The examination comprises the following subjects:—Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Sanitary Law, and Bacteriology. The fee for the examination is £10 10s. For further particulars apply to Alfred Miller, Secretary, Committee of Management; Office, Royal College of Surgeons, Dublin.

## DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns; Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than two years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital). The Dental Schools in London are the Royal Dental Hospital of London, the National Dental Hospital, Guy's Hospital Dental School, and the London Hospital Dental School. Most of the large provincial towns, where there are medical schools, have now dental hospitals.

*The Registration of Dental Students* is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies, including two years' instruction in mechanical dentistry. The two years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student, but no portion of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration. The recommendations as to the course of study and examinations adopted by the General Medical Council in November, 1909, are under revision by the Council, but consideration of them is postponed until the Departmental Committee on the Dentists Act has reported.

It is necessary for anyone practising Dental Surgery in this country to be on the Register, and no foreign qualifications are recognised, except the Dental Diploma granted in Belgium after examination by the Provincial Medical Commission, provided the holder has obtained the grade of "Candidate in Medicine" at one of the four Belgian Universities. Persons with Colonial and Foreign qualifications which have been obtained after a four years' curriculum can apply for special registration. Certain dental qualifications granted in Australia and New Zealand are also

registrable. The Royal Colleges of the United Kingdom and ten of the Universities grant degrees or licences in Dental Surgery.

### THE REGISTERING BODIES IN DENTISTRY.

*The Royal College of Surgeons of England* grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination.—This is identical with Part I. of the First Examination of the Examining Board in England. Candidates who commenced professional study on or after Oct. 1st, 1913, must pass the Preliminary Science Examination before commencing the courses required for the Second Professional Examination. II. The First Professional Examination.—The candidate must produce evidence of instruction in Dental Metallurgy and Practical Dental Mechanics. The Examination consists of Part I. (Mechanical Dentistry) and Part II. (Dental Metallurgy), the examination in Dental Metallurgy being by written paper. The parts may be taken together or separately. III. The Second Professional Examination.—This is divided into two parts: (a) the General, (b) the Dental. The General part must be passed before the Dental portion. The instruction is obtained partly at a General Hospital and partly at a Dental Hospital.—The Second Professional Examination consists of: Part I., General Anatomy and Physiology, General Surgery and Pathology; Part II., Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. There is a written and *visà voce* examination in each part and a practical examination as well in Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in Medicine or Surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and University above mentioned. The fee for the diploma is 20 guineas, and is payable as follows:—Preliminary Science Examination, 3 guineas; First Professional Examination, 7 guineas; Second Professional Examination, 10 guineas. Synopses of examinations and all further information can be obtained from the Secretary, Examination Hall, Queen-square, London, W.C. 1.

*Royal College of Surgeons, Edinburgh.*—Regulations giving a list of Preliminary Examinations recognised for obtaining the Licence in Dental Surgery, as well as of the subjects of the Professional Examinations, may be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, at 49, Lauriston-place, Edinburgh. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates must also have attended a course of instruction at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the Diploma in Surgery. In addition they will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, special courses of lectures and instruction in Anatomy and Physiology (Human and Comparative), Surgery, Pathology, Materia Medica, Dental Histology, and Practical Dental Mechanics and Metallurgy; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised Dental Hospital and School, for

three years. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the required courses. The examination embraces (1) Chemistry and Physics; and (2) Anatomy and Physiology. The fee is £5 5s. for the complete examination, and £3 3s. is payable for each division. In all cases of rejected candidates the fee for re-entry is £3 3s. Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10s., for re-entry £5 5s. The examination embraces (1) Surgery and Medicine; and (2) the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Materia Medica, Dental Mechanics and Dental Metallurgy, with a practical as well as the written and oral examinations in the subjects of Dental and Oral Surgery, Pathology, and Mechanics. The candidate will be tested in the Treatment of Dental Diseases, in Operative Dentistry, the Administration of Anæsthetics, Orthodontics, and in Prosthetic and Mechanical Dentistry. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations or other recognised examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15s. payable for the dental diploma. Fees and schedules must be lodged with the Clerk not later than one week before the examination.

*Royal Faculty of Physicians and Surgeons of Glasgow.*—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bacteriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow.

*Royal College of Surgeons in Ireland.*—Candidates for the Licence in Dental Surgery are required to pass two professional examinations. Before the First Examination the candidate must produce evidence of having attended courses in Theoretical and Practical Chemistry, including Metallurgy and Physics, at a recognised institution; of having been registered as a medical or dental student by the General Medical Council; and of having attended courses of instruction in the following subjects at a recognised school of medicine: (a) Anatomy Lectures; (b) Dissections with Demonstrations; (c) Physiology, including Dental Physiology; (d) Practical Physiology and Histology, including Dental Physiology and Histology, Human and Comparative. Before the Final Dental Examination the candidate must have been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the Mechanical Department of a recognised Dental Hospital, and have attended, at institutions recognised by the College for the purpose, the following courses of instruction: (a) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (b) Dental Mechanics. Lectures. Two courses. (c) Dental Anatomy. Lectures. One course. (d) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Two years. He must also have attended Clinical instructions at a recognised General Hospital during the ordinary teaching sessions (nine months), and have been engaged during four years in the acquirement of pro-

fessional knowledge subsequently to the date of registration as a medical or dental student. One year's bona-fide apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. He must be 21 years of age.

In the First Dental Examination candidates will be examined in (A) Physics and Chemistry, including Practical Chemistry and Metallurgy. (B) Anatomy, Physiology, and Histology—General and Dental. All the subjects may be passed at the same time, or they may be passed in two groups, (A) and (B). The examination is partly written, partly *visû voce*, and partly practical.

In the Final Dental Examination candidates will be examined in General Pathology, Medicine, and Surgery; Dental Surgery, and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery; Dental Mechanics and Metallurgy; Orthodontia. Candidates must pass in all the subjects at one examination. The examination is partly written, partly *visû voce*, and partly practical, and includes the examination of patients and the performance of dental operations. Candidates are required to provide their own instruments and gold for filling. The First Dental Examination will commence on the first Mondays in the months of February, May, and November. The Final Dental Examination will commence on the second Mondays in the months of February, May, and November. The total fee for the Diploma in Dental Surgery is 20 guineas. Candidates must pay the fees for examinations from which they are exempted, unless when such exemptions have been granted in virtue of examinations passed before the Conjoint Board in Ireland.

*University of Birmingham.*—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum and Laboratory. An Entrance Exhibition, value £37 10s. is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (a) Chemistry and Practical Chemistry, (b) Physics and Practical Physics, (c) Elementary Biology, (d) Anatomy and Practical Anatomy, and (e) Physiology and Practical Physiology. B. That he has passed the class examinations in: (f) One Special Course of Lectures on Medicine, (g) One Special Course of Lectures on Surgery, and (h) Pathology and Bacteriology. C. That he has attended courses and passed the class examinations in: (k) Dental Histology and Patho-Histology, (l) Comparative Dental Anatomy, and (m) Dental Surgery and Prosthetic Dentistry. D. That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes C and D. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work and investigations in some subject connected with Dentistry, which thesis shall be submitted to examiners to be nominated by the Dental Advisory Board.

*University of Bristol.*—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than five years, of which three shall have been passed in the University, and shall have been registered as dental students by the General Medical Council. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Zoology, and the curriculum extends over one year.\* The Second Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for two years an approved pupillage in Dental Mechanics. The Third Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall be registered dental students before being admitted to any professional examination; the curriculum extends over four years. A two years' pupillage in Mechanical Dentistry is required, and four examinations must be passed, the subjects of which differ only from those of the B.D.S. in that Zoology is not required for the First Examination, and Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

*University of Durham.*—Every candidate for the Licence in Dental Surgery must be registered as a dental student. There are four Examinations. The subjects are:—*First:* (a) Chemistry; and (b) Physics. *Second:* (a) Dental Mechanics, Theoretical and Practical; (b) Dental Metallurgy. *Third:* (a) Anatomy; (b) Physiology and Histology; (c) Dental Anatomy and Dental Histology; and (d) Dental Materia Medica. *Final:* (a) Surgery; (b) Dental Surgery, including Prosthetics and Orthodontia; (c) Operative Dental Surgery, Practical Examination; and (d) Dental Pathology and Bacteriology. A candidate before presenting himself for examination is required to furnish certificates of instruction in the following subjects, attended after registration as a dental student at recognised Colleges or Schools:—*First Examination:* Chemistry and Physics. *Second Examination:* Dental Mechanics and Dental Metallurgy. *Third Examination:* Anatomy, with Dissections; Physiology; Histology; Dental Anatomy and Physiology; Dental Histology; and Dental Materia Medica. *Final Examination:* Dental Hospital Practice (two years); General Hospital Practice (nine months); Medicine Lectures (two terms); Surgery Lectures (two terms); Dental Surgery and Pathology (a course of not less than 20 lectures); Dental Bacteriology (three terms); Operative Dental Surgery (not less than 12 lectures); and Anaesthetics (a course of not less than one month).

Before admission to the Final Examination each candidate must furnish evidence (1) of having attained the age of 21 years; (2) of having undergone a three years' pupillage in Mechanical Dentistry with a registered dentist; and (3) of having been engaged in professional study for at least four years subsequent to registration as a dental student. The examinations will be held concurrently with the medical examinations, and the fees payable by candidates are as follows: First Examination, £2 10s.; Second Examination, £2 10s.; Third Examination, £2 10s.; Final Examination, £3 10s.; fee for Licence, £3; total, £15. For re-examination: First Examination, £1 10s.; Second Examination, £2; Third Examination, £2 (in one part only, £1); Fourth Examination, £2. The practical examinations in dentistry will be conducted at the Newcastle Dental Hospital.

*University of Leeds.*—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the First Examination, and to have completed such period of pupillage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. The classes in the Department of Dentistry begin on Oct. 1st. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology are given at the University in College-road. The classes in the other subjects and the systematic courses in Dental subjects are held in the School of Medicine of the University in Thoresby Place. The clinical instruction is given in the Dental Department of the Leeds Public Dispensary, which is affiliated with the University and recognised by the Royal College of Surgeons. Applications for the prospectus should be made to the Dean of the Faculty of Medicine.

*University of Liverpool (Liverpool Dental Hospital Clinical School and School of Dental Surgery).*—The University grants a Licence in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes' walk from the Dental Hospital. The two institutions are now closely associated, and the management of the curriculum is in the hands of the Board of Dental Studies. The Dental Hospital, covering a site of 672 square yards, is equipped in each department with every modern accessory and receives constant additions. The laboratory is in charge of a skilled dental mechanic under the supervision of the Director of Dental Education and Dental Staff, and students are able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lectures at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. Fees: The composition fees are as follows: Licence course (L.D.S.): Composition fee £58 10s., for the course of other licensing bodies £61 10s., payable in two equal instalments, the first on entry, the second 12 months later. Two years' instruction in Mechanical Dentistry (pupillage) and two years' Dental Hospital Practice (combined), £100, or in two instalments of £52 10s. each. Degree course (B.D.S.): £67 10s. for all lectures (including Chemistry, Physics, and Zoology) in three instalments. Two years' dental hospital, £21; general hospital practice, £10 10s.; three years' mechanical instruction (pupillage), £105. Further information may be had from the Director of Dental Education, Mr. W. H. Gilmour.

*University of Manchester.*—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any otherschool in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given during the Winter and Summer Sessions both at the University and at the Dental Hospital of Manchester adjoining the University. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department, and for them common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 60 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. The composition fee for candidates for the University Diploma in Dentistry is 55 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. The composition fee for candidates for the L.D.S. of England is 60 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. Students who have already served their apprenticeship with a private

\* Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The composition fee does not include the hospital fees, the examination fees, the fee for the conferment of the degree or the diploma, the registration fee, nor the fees for chemicals and chemical apparatus.

*National University of Ireland.*—This University grants the degrees of Bachelor of Dental Surgery and a degree of Master of Dental Surgery. A student may not be admitted to the Degree of Bachelor of Dental Surgery unless a period of not less than four years shall have elapsed from the date of his matriculation, during which period he must have pursued an approved course of study of not less than nine terms. For the degree of Bachelor of Dental Surgery candidates must pass four examinations, the first two being the same as those for the first and second examination in Medicine. The subjects of the third examination are Dental and Practical Pathology, Dental Surgery and Dental Medicine, the subjects of the fourth being Dental Surgery and Pathology, Dental Mechanics, Operative Dentistry, Orthodontia, and Dental Materia Medica. A candidate for the degree of B.D.S. must produce evidence of having been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under professional direction in the mechanical department of a dental hospital approved by the University. A portion of or the entire period may be served before commencing study for the degree of B.D.S., but no portion so taken prior to commencement of study shall count as part of the four years of Dental Study. The degree of Master of Dental Surgery will not be granted until three years after the B.D.S. has been obtained.

*University of Melbourne.*—Degrees of Bachelor (B.D.Sc.) and Doctor of Dental Science (D.D.Sc.) are granted. Candidates for the former are required. Subsequently to matriculation (which must include physics) to take a four years' course of study and to pass four examinations. They shall be apprenticed for not less than three years with a registered dentist in some part of the British Empire. Fee for the four years £100, payable in four equal annual instalments. Annual examination fee £5 5s. Candidates for the degree of Doctor must be Bachelors of Dental Science of at least two years' standing. The examination is partly written and partly oral. A thesis may be submitted.

*University of Sydney.*—A degree in Dental Surgery (B.D.S.) is granted after a four years' course following matriculation. A graduate in medicine is required to devote four terms to dental study before sitting for the degree of B.D.S. and a licentiate in dental surgery one additional year.

*University of Adelaide.*—The four years' course for the B.D.S. is regulated by similar conditions to that for the M.B., B.S. Four examinations are held in November of successive years. The fee for each ordinary examination is £3 3s., and for the degree £5 5s. Fees for the whole course amount to £95 11s.

*McGill University, Montreal.*—The degree of D.D.S. is granted on a four years' curriculum, the first year being that demanded of students in the Medical Faculty.

*University of Toronto.*—The degree of D.D.S. is granted on a four years' curriculum. Annual examinations are conducted under the joint auspices of the University and the Royal College of Dental Surgeons of Ontario. Concurrent courses may be run in medicine and dentistry extending over seven years.

*University of Malta.*—The University grants its diploma in dental surgery after examination to candidates producing evidence of four years' professional study and three years' instruction in mechanical dentistry.

See also under Universities of Birmingham, Leeds, Liverpool, and Manchester above.

#### LONDON.

*Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.*—A school of the University of London, and women are now admitted as students and are eligible for all hospital appointments and school prizes.—The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the

curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The six house surgeons are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £50. One Entrance Scholarship in Dental Mechanics and Metallurgy value £25, open to pupils of the Hospital only. One Entrance Scholarship of £25 in Dental Mechanics, open to pupils of private practitioners. The Saunders Scholarship of £20 awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. Fee for two years' hospital practice required by the curriculum, including lectures, £53 3s. in one payment, or £55 13s. in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £60. Both hospitals can be attended simultaneously. For the lectures in Chemistry and Physics for the Preliminary Science Examination £10 10s. The fee for the instruction in Dental Mechanics and the two years' hospital practice required by the curriculum is £150 if paid in one instalment, or 150 guineas if paid in three equal instalments. The fee for tuition in Dental Mechanics is 50 guineas per annum; for one year's hospital practice £21. The Winter Session opens on Oct. 1st.

*University College Hospital Dental School.*—Corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Chemistry, Physics, Anatomy, and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the National Dental Hospital. The First Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. Two Entrance Exhibitions, of the value of £40 and £20, are open for competition. Prizes are open for competition at the end of each course of lectures. Fee for the full curriculum of four years, in all subjects required by the Royal College of Surgeons, also for other licensing bodies, 180 guineas, or in four instalments of 62, 41, 41, 41 guineas. A composition fee for medical men has been arranged covering the Two Years' Mechanical Work, Hospital Practice, and Lectures required by the curriculum of the Royal College of Surgeons amounting to 120 guineas. Hospital Practice to registered practitioners by special permission of Committee. 12 months, £15 15s. The Calendar, containing full information as to Lectures, Fees, Prizes, and Subjects for the Entrance Exhibitions may be had on application to the Dean, who attends the Hospital on Tuesday mornings at 10.30.

*Guy's Hospital.*—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: A new Dental Out-patient Department has been provided. There is ample accommodation for ordinary extractions and anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrator, the dental house surgeon, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It has recently been entirely remodelled and greatly enlarged, giving a floor space of over 6000 square feet. It affords accommodation for about 100 dental chairs, with the necessary equipment of the

most modern type, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by two of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out. Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the L.D.S. Eng.—viz., two years' studentship in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Four Entrance Scholarships in Dental Prosthetics of the value of £20 each are offered for competition annually, two in September and two in April, and prizes of the aggregate value of £47 are awarded for general proficiency and for skill in Operative Dentistry. A Dental Travelling Scholarship of the value of £100 is awarded every second year. Dental students are eligible for admission to the Residential College and enjoy the privileges of students in the Medical School. Application should be made to the Dean of the Medical School.

*London Hospital.*—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoon at every chair has been specially designed and has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses in addition to the Theatres, Laboratories and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Dental Metallurgy and Dental Prosthesis. A systematic course of instruction in Dental Prosthesis is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to fees and course of study advised apply to the Dean, Professor William Wright, who will be glad to make arrangements for anyone wishing to see the Dental School and Medical College.

*London (Royal Free Hospital) School of Medicine for Women.*—Full courses are arranged for women students for the study of dentistry, and in preparation for the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women, in conjunction with the London Dental Hospital, Leicester-square, and the National Dental Hospital, Great Portland-street, W. The course is arranged as follows: First and second years: Chemistry, Physics, and Dental Mechanics. Third, fourth, and fifth years: Anatomy, Physiology, and Special Dental Courses, Courses in Medicine and Surgery, General Hospital Course, Dental Hospital Course. The combined fees at the London School of Medicine for Women and the National Dental Hospital are £180 if paid in one sum on beginning the course, or £191 if paid in three annual instalments. Bursary: The Council of the School will award annually (until further notice) an "Agnes Guthrie" Bursary of the value of £50 to a student fulfilling the required conditions, who enters for the full dental course. Candidates are required to send in applications on or before July 1st, to the Warden and Secretary, from whom a prospectus of the School and all particulars can be obtained.

## PROVINCIAL.

*Birmingham Dental Hospital, Great Charles-street.*—Dean: Mr. W. T. Madin. The Dental Hospital was founded in 1858, and was recognised by the Royal College of Surgeons in 1880 for the teaching of Dental Students. Having an annual attendance of about 16,000 patients, it affords every advantage for students about to enter the profession to acquire a thorough practical knowledge, as required by the Medical Council. The present Hospital was opened on July 6th, 1905. It has accommodation for 50 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery. The operations performed annually average 35,000, including 5000 gold and other fillings, and many cases of crowns, bridges, porcelain inlays, and regulations. By arrangements with the Birmingham University and with the General and Queen's Hospitals the entire course of Lectures, Hospital Practice, &c., may be completed for an inclusive fee of £96 15s., or including Mechanical Pupilage, £186. Examination fees for L.D.S. Birm., total £18. The instruments and materials necessary for Hospital Practice cost about £35. The Composition Fee for the courses required for the L.D.S. of the University, or any of the Corporations alone, is £60, payable in two annual instalments at the commencement of the first and second years; that for the courses required for the L.D.S. and the Degree in Dentistry of the University is £75; that for the L.D.S. in combination with the M.R.C.S. and L.R.C.P. is £85; and that for the M.B., Ch.B., and B.D.S. is £95. All of these composition fees are payable in two annual instalments at the commencement of the first and second years. Each of these fees covers the cost of the courses given at the University for the qualifications indicated, but does not include fees for Hospital teaching. For two years' dental hospital practice the fee is 20 guineas, payable in two instalments of 10 guineas each at the commencement of the first and second (hospital) years respectively. For two years' mechanical pupilage, 85 guineas, which may be paid in two annual instalments of 50 and 35 guineas respectively; mechanical pupils may join for a probationary period of one month, fee 5 guineas, which is deducted upon payment of the full amount. For general surgical hospital practice, lectures, and demonstrations: Surgery, two winters, £10 10s. One Entrance Scholarship is offered annually of the value of £37 10s. It is awarded to the student who, entering for the Dental Degree of the University in October, or having entered not earlier than the previous April, shall pass the best examination in the subjects studied during his apprenticeship. Candidates must be under the age of 21 years. Application for admission, together with a certificate of birth, must be sent to the Dean of the Medical Faculty, Mr. William F. Haslam, on or before Oct. 15th.

*Leeds Public Dispensary.*—The Dental Department of the Leeds Public Dispensary is fully equipped to provide training for Dental Students, and affords every opportunity for the student to prepare for any of the Dental Degrees or Diplomas. The Demonstrator of Operative Dental Surgery instructs students during their probationary course. At the completion of this training students have patients allotted to them by the Demonstrator, and have every opportunity of acquiring knowledge from the members of the Staff, two of whom are in attendance each day. The following prizes are awarded:—First year Students, value 2 guineas. Operative Dental Surgery Prize, value 5 guineas. Two prizes in Prosthetic Dentistry: (a) a prize, value 2 guineas, for first-year pupils; (b) a prize, value 5 guineas, open for competition to all Students. Extraction prize, value 2 guineas, open for competition to all Students. A prize in Orthodontics, value 5 guineas, is open to all students. Warden: Mr. W. Sinton Thorburn, to whom all communications should be addressed.

*Dental Hospital of Manchester.*—This Hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to meet the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of Surgeons of England. Clinical instruction is given by the members of the staff and by the house surgeons and demonstrators, and also by the honorary

anæsthetists in the administration of nitrous oxide gas; a special class in anæsthetics is conducted by the clinical tutor in that subject, and a class for instruction in porcelain and gold inlay work by the demonstrator specially appointed for that work.

A Travelling Scholarship, value £100, will be awarded from time to time. Ten prizes, varying in value from £2 to £8, are awarded annually.

For the whole course of hospital instruction for the L.D.S. (including two years' mechanical training) the fee is £100, or if paid in instalments £105. For the two years' Operative Course only, £21, or if paid in two instalments 21 guineas. For the whole course of hospital instruction for the B.D.S. degree (including mechanical training), £130, or if paid in instalments 130 guineas. Additional practice in Dental Mechanics may be taken by pupils who have already received their mechanical training elsewhere, at a fee of £20 for six months.

All the courses of instruction are open to women students.

Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

*Newcastle-upon-Tyne Dental Hospital and School.*—This Hospital is centrally situated (within five minutes of the various colleges, infirmary, and railway station); the rooms are well lighted and thoroughly equipped for carrying on the work. Dental surgeons and an anæsthetist attend each morning. A tutorial dental surgeon is also in attendance. The Composition Fee for the special Dental Lectures and Dental Hospital Practice is £45 3s. if paid in one sum, or £46 4s. if paid in two instalments of £23 2s. The Composition Fee for the Lectures at the Colleges of Medicine and Science is 40 guineas; in addition to this there is a library and an athletic fee. Particulars of the fee for General Hospital Practice may be obtained from the Senior House Physician, Royal Victoria Infirmary, Newcastle-upon-Tyne. Medals and Certificates of Merit are granted to students showing certain standards of proficiency in the various classes at the Dental School. The prospectus of the Dental Hospital and School, containing full information, may be obtained from either Mr. J. T. Jameson, 12, Windsor-crescent, Newcastle-upon-Tyne, Dean, or Mr. James Coltman, 13, Ellison-place, Newcastle-upon-Tyne, Vice-Dean.

*Devon and Exeter Dental Hospital, 24, Southernhay, West, Exeter.*—Established 1880.—The hospital is open on Mondays, Tuesdays, Wednesdays, and Thursdays, and patients are admitted between the hours of 9 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers. Honorary treasurer, Mr. J. M. Ackland; secretary Mr. Albert G. Littlejohn.

#### SCOTLAND.

*The Incorporated Edinburgh Dental Hospital and School.*—The Edinburgh Dental Hospital and School is located in a spacious and well-equipped building at 31, Chambers-street and offers special advantages to dental students. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. The cost of the hospital outfit of instruments is included in the Dental Hospital fee of £42. The minimum cost of classes and Diploma for the whole course of dental instruction amounts to £98 17s. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow

is recommended. The minimum cost of Professional Education, the Triple Qualification, and the Licence in Dental Surgery amounts to £172 19s. Further particulars can be obtained from the Dean, Mr. W. Guy.

*Incorporated Glasgow Dental Hospital, 15, Dalhousie-street, Glasgow.*—The School is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Pathology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, and Anæsthetics. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extra-mural schools where special provision is made for Dental Students. Composition fee for two years' Hospital Practice and Lectures special to Dentistry, £40 on entry or in two instalments of £21 each. Fees for Hospital Practice and Dental Lectures may be paid for separately, at a total cost of £43 1s. Full information may be had on application to the Dean.

*Glasgow Royal Infirmary (Dental Department).*\*—Mr. W. Taylor attends at the Royal Infirmary at 9 A.M. on Wednesdays and other days as arranged, and gives a course of instruction in Dental Surgery. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital.

#### IRELAND.

*Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.*\*—All Dental Students who have passed their First Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica. Practical instruction is also given in Anæsthetics. In addition to the longer courses of hospital attendance, courses of three months' duration will be given to surgeons intending to practise in the Colonies or remote country districts, or in the Army and Navy.

Fees.—Dental Hospital Practise (each year), £12 12s.; Lectures, £6 6s.; Composition Fee, £15 15s. per annum. In addition to the above courses registered dentists who are members of the British Dental Association will usually be permitted to take out a three months' course for a fee of 6 guineas. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

#### DOMINIONS.

*The Australian College of Dentistry*, in connexion with the Melbourne Dental Hospital, trains candidates for the degrees of B.D.Sc. and D.D.Sc. Melb. Students indentured to the College pay £170 in two instalments of £85 each, or four instalments of £42 10s. The superintendent of the College is Mr. E. S. Fisher, L.D.S., D.D.Sc.

*United Dental Hospital of Sydney* was established in 1901 to provide facilities for the students attending the University Dental School. The fee payable by University students for the dental practice of the hospital is £6 6s. per annum. The secretary is Mr. H. A. Clarke, F.I.A.A.

*The Dental Department of McGill University, Montreal*, was opened in 1903 at the request of the Dental Association of the Province of Quebec as a section of the medical faculty. An out-patient clinic in dentistry at the Montreal General Hospital provides the clinical material. Particulars from the Registrar of the Medical Faculty.

*The Royal College of Dental Surgeons of Ontario* has a school of dentistry in connexion with the University of Toronto. Practical work is carried out in the infirmary and laboratories of the College.

\* No returns.

## REGISTRABLE COLONIAL AND FOREIGN MEDICAL DEGREES.

UNDER the Medical Act, 1886, a number of medical diplomas granted in British possessions entitle their possessors to be registered without further examination in the Colonial List of the (British) Medical Register. The condition attached to such registration is that the holder of the colonial diploma obtained it when he was not domiciled in the United Kingdom or in the course of a period of not less than five years during the whole of which he resided out of the United Kingdom. Some account<sup>1</sup> of these diplomas is here given.

### AUSTRALASIA.

*Summary of Registrable Degrees.*—New South Wales: University of Sydney, (1) M.B., (2) M.D., (3) Ch.M. New Zealand: University of New Zealand, (1) M.B., Ch.B., (2) M.D. South Australia: University of Adelaide, (1) M.B., B.S., (2) M.D., (3) M.S. Victoria: University of Melbourne, (1) M.B., (2) M.D., B.S.

### University of Adelaide.

The University of Adelaide<sup>2</sup> was established by Act of the South Australian Legislature in 1874. In 1883 Sir Thomas Elder gave £10,000 for the foundation of a school of medicine. The Medical Acts of 1844 and 1880 set up a South Australian Medical Board to issue certificates of legally qualified medical practice.

*Preliminary Examination.*—Before entering upon the medical course candidates must have passed the Senior Public Examination in at least five subjects at one and the same time, and the higher standard in physics, chemistry, and biology.

*M.B., B.S.*—The five years' course includes five examinations held in November of each year. At the first the subjects are anatomy and dissections, physiology, organic chemistry, and physical chemistry; at the second, anatomy, physiology, and materia medica; at the third, medicine, surgery (including clinical), regional and surgical anatomy, bacteriology; at the fourth, medicine (including clinical), surgery, pathology, obstetrics, and forensic medicine (including insanity); at the fifth, medicine (all branches), surgery (including surgical anatomy and operative surgery), gynaecology, ophthalmology, otology, therapeutics, and elements of hygiene. The fee for each examination is £3 3s. and for the degree £5 5s. Fees for the five years' course of study amount to £124 19s. There were 189 undergraduate students in 1918.

*M.D.*—Candidates must have been Bachelors for at least nine academic terms, which may be shortened on the recommendation of the Faculty of Medicine. The subject of examination may be selected from the following: General medicine, diseases of the nervous system, pathology, obstetrics, State medicine. A thesis may be submitted. Fee for the examination £15 15s., for the degree £10 10s.

*M.S.*—The conditions are similar to those for the M.D. Choice of subject may be made from: Gynaecology, the surgery of the abdomen, the surgery of the special senses and throat; in addition to examination in the principles of surgery.

### University of Melbourne.

The University of Melbourne<sup>3</sup> was incorporated by Act of the Victorian Legislature in 1853. The Medical Act of 1890 set up the Medical Board of Victoria to register legally qualified medical practitioners.

*Preliminary Examination.*—All candidates must possess the School Leaving Certificate, which is based on education in a secondary school during four years. The Intermediate Certificate must have been taken at least a year before the School Leaving. English is compulsory at the higher standard; Latin and geometry with trigonometry at the lower.

<sup>1</sup> The information which was kindly sent to us has been summarised. Where none appears none was received. It is hoped to make the section more complete another year.

<sup>2</sup> The University Registrar is Mr. C. R. Hodge. The Calendar of the University of Adelaide (1919) is a volume of 490 pp., printed by W. K. Thomas and Co., Grenfell street, Adelaide. Price 2s. 6d.

<sup>3</sup> The University Registrar is Mr. J. P. Bainbridge, J.P. The Melbourne University Calendar (1919) is a volume of 334 pp., printed for the University by Ford and Son, Drummond-street, Carlton, Melbourne. Price 3s.

*M.B., B.S.*—The course extends over five calendar years, and is divided into two equal parts, hospital practice being confined to the second half. The first year (Division I.) is devoted to natural philosophy, chemistry, biology, and botany; the remainder of the first half (Division II.) to anatomy and physiology. Two complete courses of dissections are compulsory. Hospital practice extends through Divisions III. and IV. The general hospitals ranking as clinical schools are the Melbourne Hospital, the Alfred Hospital, and the St. Vincent's Hospital. The recognised special hospitals include the Women's Hospital, the Children's Hospital, the Eye and Ear Hospital, the Infectious Diseases Hospital, the Receiving House, and Acute Mental Hospital. A full clinical curriculum is arranged, both general and special, with clinical lectures. In Division III. (lasting one year) courses of lectures are given in pathology (with practical work in histology and in bacteriology), in therapeutics, public health, materia medica, and pharmacy, and regional and applied anatomy, and examination in all these subjects follows immediately. In Division IV., lasting a year and a half, systematic lectures are confined to the first year and include medicine, surgery, and forensic medicine. Lectures on obstetrics and gynaecology are given in Division III., but the examination in these subjects is postponed till the final at the end of the course, which also includes the subjects of Division IV. Clinical medicine and clinical surgery rank as separate subjects in the finals.

Honour examinations with exhibitions are held in all subjects of Divisions I., II., and III., and there is a final honour examination with scholarships in medicine, in surgery, and in obstetrics and gynaecology.

The yearly fee payable to the University is £23, with a sports fee of 1 guinea and a club-house fee of 1 guinea. The hospital and pharmacy fees in Divisions III. and IV. amount to £69 6s. The total fees are £194 16s. The degree fee for M.B., B.S., is 7 guineas.

The number of students now in attendance is 628.

*M.D.*—Candidates must be Bachelors of Medicine of two years' standing. They may proceed either by thesis or by examination. The thesis must be a substantial contribution to medical knowledge. The examination includes medicine, with either obstetrics and medical gynaecology, or diseases of children, or diseases of the nervous system, including insanity. Subject to a dispensing power in the case of theses of great merit, all candidates must pass an examination in clinical medicine. The fee for examination and degree is 10 guineas.

*M.S.*—Candidates must be Bachelors of Surgery of two years' standing. Part I. of the examination includes surgical anatomy and surgical pathology. Part II. includes surgery in all branches. The two parts may be taken together or separately. No candidate can pass in Part II. who has not passed in Part I. The fee for examination and degree is 10 guineas.

*Diploma of Public Health.*—Granted under conditions agreeing with those in the United Kingdom. Fees for instruction are 32 guineas, apart from fever hospital practice. The fee for examination is 10 guineas, for diploma 3 guineas.

*Diploma of Tropical Medicine.*—Candidates must be qualified medical practitioners, and must have passed Part I. for D.P.H. or have undergone a special training in lieu thereof. They are trained in tropical medicine at the Australian Institute of Tropical Medicine, Townsville, Queensland, having a three months' course of theoretical and practical instruction, followed by a three months' clinical course in the Townsville Hospital. The examination is conducted at the institute. Fee for preliminary course is £2 2s.; for course at institute, 10 guineas; for examination and diploma, 5 guineas.

*Affiliated Colleges.*—Trinity College (1872), Ormond College (1879), and Queen's College (1888) are affiliated to the University and have medical tutors.

### University of New Zealand.

The University of New Zealand was established by Act of the New Zealand Legislature in 1870. The Medical Act of 1908 provided for the registration of medical practitioners. The University has no fixed home or buildings; it is an examining body with four affiliated colleges—namely, University of Otago, Dunedin; Canterbury College, Christchurch; Auckland University College; and Victoria

University, Wellington. The degrees of M.B., Ch.B., M.D., and B.D.S. are conferred.

#### *University of Sydney.*

The University of Sydney<sup>1</sup> was incorporated by Act of the New South Wales Legislature in 1850. The Medical Practitioners Act of 1898 provides for the registration of legally qualified medical practitioners.

*Matriculation Examination.*—Latin and another language other than English are required, one at the Higher standard.

*M.B., Ch.M.*—The course of study extends over a period of five years. Five degree and a final examination are held: (1st year) in physics, chemistry, botany and zoology; (2nd year) in anatomy and physiology; (3rd year) in the entire subjects of anatomy and physiology, every part of the body having been dissected at least once; (4th year) in pathology, surgical anatomy and operative surgery, materia medica, and therapeutics; (5th year) in medical jurisprudence and public health; (final) in medicine, surgery, obstetrics, and gynaecology. Certificates of proficiency in vaccination and anaesthetics are required. The fee for each degree is £10. The number of students attending degree courses during 1917 was 545—480 men and 65 women.

*M.D.*—Candidates must, after obtaining the degree of Bachelor, have spent at least two years in medical or surgical practice or in approved study. Examination is written or oral in one of the following subjects: medicine, medical jurisprudence and public health, surgery, obstetrics and gynaecology; or in any of the scientific subjects included in the medical curriculum. A thesis must be presented two months before the examination. The fee for the degree is £10.

*Diploma in Public Health.*—Candidates must be registered practitioners of not less than 12 months' standing. The examination is in two parts: (1) relating to the general principles of sanitary medicine; (2) relating to State medicine and to the applications of pathology and sanitary science to public health. The fee is £10.

*Affiliated Colleges.*—Matriculated students are admitted to the following resident colleges—namely, St. Paul's College (Church of England), St. John's College (Roman Catholic), St. Andrew's College (Presbyterian), Wesley College (Methodist), the Women's College (undenominational), at which scholarships and bursaries are available.

*Recognised Hospitals* are the Royal Prince Alfred Hospital with medical school, the Sydney Hospital with clinical school, St. Vincent's Hospital, the Royal Hospital for Women, the Royal Alexandra Hospital for Children, the Glandesville and Callan Park Hospitals for the Insane, the Women's Hospital, the Renwick Hospital for Infants, and the South Sydney Hospital for Women.

#### BRITISH NORTH AMERICA.

*Summary of Registrable Degrees and Diplomas.*—Manitoba: College of Physicians and Surgeons, Member; University of Manitoba, M.D. New Brunswick: Provincial Council of Physicians and Surgeons, L.M.S. Newfoundland: Medical Board, L.M.S. Nova Scotia: Provincial Medical Board, L.M.S.; Dalhousie University, M.D., C.M. (Halifax Medical College, M.D., C.M., if obtained prior to August 31st, 1911). Ontario: College of Physicians and Surgeons, Member. (To this can be added as additional qualifications the degrees in medicine of the Queen's University, Kingston; the Western University, London; and the University of Toronto.) Prince Edward Island: Medical Council, L.M.S. Quebec: McGill University, M.D., C.M.; Laval University, M.D. Saskatchewan: College of Physicians and Surgeons, Member.

#### *Dalhousie University, Halifax, Nova Scotia.*<sup>5</sup>

The work of Halifax Medical College was discontinued in 1911, when instruction in all subjects of the medical curriculum was undertaken by Dalhousie University. The professional examinations are conducted conjointly by the university and the Provincial Medical Board of Nova Scotia (see below).

<sup>4</sup> The University Registrar is Mr. H. E. Barff, M.A. The Calendar of the University of Sydney (1918) is a volume of 712 pp., printed for the University by Angus and Robertson, Ltd., Sydney. Price 2s. 6d.

<sup>5</sup> The Secretary of the Medical Faculty is Professor D. Fraser Harris. The calendar of the Faculty, 1919-20, is an excerpt of 40 pp. from the University Calendar, printed for the University by Wm. Macnab and Son, Halifax.

*M.D., C.M.*—In addition to the matriculation or preliminary examination candidates are required to pass five professional examinations. For admission to the classes of the third or any higher year the undergraduate must have passed in all the subjects of the preceding year. The curriculum for the third year still includes practical anatomy and advanced physiology, while the fifth (final) year subjects are given as: Surgical anatomy, operative surgery, clinical surgery, clinical medicine, clinical pediatrics, clinical obstetrics, practical obstetrics, clinical gynaecology, mental diseases, skin diseases, eye, ear, nose and throat diseases, dressing, clerking, vaccination, post mortems, hospital, medical ethics. To win distinction in any subject a mark of 75 per cent. or over is required. The total tuition fees in any year amount to \$125, with \$10 additional for the third, fourth, and fifth years. The fee for each examination is \$10. There were 114 medical students of all years in 1918-19.

#### *Queen's University, Kingston, Canada.*

Queen's College, Kingston,<sup>6</sup> was established by Royal charter in 1841, assisted by grants from the Presbyterian Church in Scotland. Classes in medicine were first held in the University in 1854. The Medical School, conducted for a time under the charter of the Royal College of Physicians and Surgeons at Kingston, became an integral part of the University in 1892. Kingston General Hospital (230 beds) is adjacent to the University buildings.

*M.D., C.M.*—Candidates for a degree must pass the Junior Matriculation of the University or its equivalent. The course comprises five sessions of eight months each. A combined B.A. and M.D. course may be taken in seven years. Foreign students must spend at least one full session in the University. Examinations are held at the end of each session. The average cost per session of eight months, including board and lodging, is \$376-\$435. All students are expected to attend a church of the denomination to which they profess to belong. 228 students were in attendance during the session 1918-19.

*D.Sc.*—Granted on a thesis embodying original research of importance to medical science not earlier than two years after graduation. A reading knowledge of scientific French and German is required.

*D.P.H.*—The diploma is granted to those holding the M.D., or M.D., B.Sc., after examination following prescribed study, which includes six months with a recognised medical officer of health in the study of practical sanitation.

#### *Laval University, Quebec.*

Laval Catholic University<sup>7</sup> was incorporated by Royal Charter in 1852, absorbing the Quebec School of Medicine organised four years earlier. The first class graduated in 1855.

*M.B., M.D.*—The entrance examination includes Latin, philosophy, and Canadian history, and its standard is prescribed by the College of Physicians and Surgeons of Quebec. The Faculty of Medicine confers a baccalauréat and a doctorat, the former after 2 years, comprising 6 terms of study, the latter after 3 further years. Examinations are held in June at the end of each year of study. The total fee for examinations is \$15, for the diploma of bachelor \$5, and for that of doctor \$20. Fees paid by enrolled students for the medical course amount to \$45 a term.

#### *McGill University, Montreal.*

"The Faculty of Medicine of McGill University" arose out of the Montreal Medical Institution, organised as a medical school in 1823-24, and incorporated in the University in 1829.

*Preliminary Examination.*—Before registration an undergraduate in medicine must have passed the Matriculation Examination of the University or its equivalent. The examination is held twice yearly at McGill, and once at Calgary, Regina, Winnipeg, Toronto, St. John, and Truro.

<sup>6</sup> The Secretary of the Medical Faculty is Dr. A. R. B. Williamson. Queen's University, Kingston, Ont. The Calendar of the Faculty of Medicine, 1919-20, is a volume of 104 pp., printed by the Jackson Press, Kingston.

<sup>7</sup> The Secretary of the Medical Faculty is M. Arthur Vallée. The Annuaire de la Faculté de la Médecine de l'Université Laval (1918-19) is a volume of 61 pp., printed by l'Action Sociale, Limitée, Quebec.

<sup>8</sup> The University Registrar is Mr. J. M. Nicholson, M.A. The registrar of the Faculty of Medicine is Dr. J. W. Scane. The Annual Calendar of the Faculty of Medicine and Department of Dentistry is a volume of 90 pp., printed by the Gazette Printing Co., Ltd., Montreal.

Also in June in London (apply to Secretary, Headmasters' Conference, 12, King's Bench Walk, E.C.). Latin, and either Greek, French, or German must be taken. Every student entering the University is required to pass a physical examination to detect defects and weaknesses amenable to treatment. Board and lodging can be obtained in private houses in the vicinity of the University at \$40 a month upwards.

*M.D., C.M.*—The undergraduate course in medicine has this year been increased to six years by a pre-medical year devoted to chemistry, physics, and biology, with English and one modern language. This readjustment gives a final year confined to hospital work, including medicine, surgery, obstetrics, ophthalmology, oto-laryngology, pathology, and dermatology. The third year now embraces anatomy (neurology), physiology, general pathology, bacteriology, chemistry (physiological and clinical), parasitology, pharmacology, and clinical microscopy. During this year students begin to visit the hospitals and receive instruction in small groups in the elements of clinical medicine and clinical surgery. Examinations are held in the subjects of each successive year. Seven years' (double) courses are held for the B.A., M.D., or B.Sc., M.D. The total faculty fees for the medical course of five years are \$735, payable in five annual instalments of \$147 each. The degree fee is 30. 365 medical students were enrolled in the session 1917-18.

*D.P.H.*—The course for this diploma is temporarily withdrawn.

#### *New Brunswick, Council of Physicians and Surgeons.*

The Council of Physicians and Surgeons of New Brunswick is empowered by the Medical Act to issue a licence (L.M.S.) conferring the legal right to practise. The usual matriculation examination is required and the graded collegiate course comprises five sessions of not less than eight months each. The examinations are held twice a year at St. John, N.B., the fee being \$30. Candidates may appear for the primary examination at the end of the second year of study. The fee for the licence is \$3 and the registration fee \$40. The registrar of the council is Dr. S. Skinner, 64, Charlotte-street, St. John, N.B.

#### *Nova Scotia, Provincial Medical Board.*

A licence (L.M.S.), legally entitling to practise, is issued by the Provincial Medical Board of Nova Scotia after a preliminary (fee \$25 including student registration) and three professional examinations (fees \$75 including registration). The registrar of the Board is Dr. W. H. Hattie, Halifax, N.S.

#### *University of Toronto.*

The University of Toronto,<sup>9</sup> Ontario, took its title in 1849, a Royal Charter having been granted in 1827. The Faculty of Medicine was re-established in 1887 under the Federation Act. Victoria College (1892), Trinity College (1904), and St. Michael's College (1907) are integral parts of the University.

*Preliminary Examination.*—The matriculation certificate of the University is required from entrants unless they are graduates in Arts of a Dominion or British University or possess a certificate of entrance into the Faculty of Education.

*M.B.*—The undergraduate course has just been lengthened to six years, with an exception for those who have been on military service. Six examinations are taken in succession at the end of the session. The early years aim at giving such a training in sciences as is now exacted of those who desire to obtain a British as well as a Canadian qualification. During the third year an attempt is made to bridge the gap between the primary scientific and the final clinical subjects by taking up anatomy and physiology at the same time as surgery and medicine throughout the year. Preliminary courses in pathology and pathological chemistry are taken; instruction is given in pharmacology; and a series of ten lectures delivered on psychology. The final year includes courses on anaesthesia, dentistry, medical ethics, history of medicine, and life insurance. The annual fee for regular students with one annual examination is \$150. Combined courses of B.A., M.B. and B.Sc., M.B., lasting seven years, are also arranged. Honour standing can be obtained in each year's subjects. There is residence for about 150 men and

three houses near to the University. Each male student proceeding to a degree must take physical training, the character to be determined by medical examination in the first two years of his attendance.

*M.D.*—One year must elapse after obtaining the M.B. degree and an approved thesis submitted.

*D.P.H.*—Candidates must be graduates in medicine of this or some other University. The curriculum extends over a winter session of eight months and a summer session of three months. The fee for the course is \$150 and for the diploma \$20.

#### NEAR EAST.

##### *Registrable Degree.*—University of Malta, M.D.

##### *University of Malta.*

The University of Malta was added in 1898 to the list of institutions recognised by the English Royal Colleges. Study in the Faculty of Medicine and Surgery<sup>10</sup> is open to matriculated students who have attended a three years' preparatory course in the Faculty of Science. Matriculation includes English, Italian, and Latin, while history is also necessary to comply with the G. M. C. regulations. The preparatory course in science in its third year comprises English or Italian literature, physics, organic chemistry, and human anatomy and general histology, with dissection. Medical botany is taught at the Botanic Garden. The academical course of medicine and surgery (*M.B., Ch.B.*) extends over four years, the first year being devoted solely to anatomy and physiology, and the final year including clinical medicine, surgery, and midwifery, along with operative surgery and forensic medicine, and continued attendance at the clinical laboratory and the hospital. The degree of *M.D.* or of *Ch.M.* is conferred on any *M.B., Ch.B.* on passing an examination at not less than one year after graduation, in each case with an approved thesis. The fee for any of the three degrees is £6.

#### FAR EAST.

*Summary of Registrable Degrees.*—Ceylon: Medical College, L.M.S. Hong-Kong: University of Hong-Kong, M.B., B.S. India: University of Allahabad, M.B., B.S.; University of Bombay,<sup>11</sup> (1) L.M.S., (2) M.B., B.S., (3) M.D., (4) M.S.; University of Calcutta, (1) L.M.S., (2) M.B., (3) M.D., (4) M.S., (5) M.O.; University of Madras,<sup>12</sup> (1) M.B., M.S., (2) M.B., B.S., (3) M.D.; Punjab University, (1) L.M.S., (2) M.B., (3) M.D., (4) M.S. Straits Settlements: King Edward VII. Medical School, Singapore, L.M.S.

##### *University of Allahabad.*

The examination for the degree of *M.B., B.S.* consists of three parts: preliminary scientific, first degree, and final degree. The two latter are held at Lucknow. The preliminary scientific examination in chemistry, physics, and biology is open to candidates who have passed in these subjects at the intermediate examination of the University. The first degree examination comprises anatomy, physiology, and materia medica and pharmacy; it may be taken after two years. The final degree examination comprises two groups: (A) midwifery, hygiene, and medical jurisprudence, taken after two years; (B) medicine, surgery, and pathology, taken a year later. Honours may be obtained in any subject. The *M.D.* degree is obtained within not less than one year on passing an examination in medicine and pathology. The fees for the *M.B., B.S.* examination are Rs.140, for the *M.D.* Rs 200.

*King George's Medical College, Lucknow,* prepares students for the medical degrees of the University of Allahabad. The curriculum extends to five college years, each of three terms. Scholarships and bursaries are granted.

##### *University of Bombay.*<sup>13</sup>

Candidates for the *M.B., B.S.* must have passed the previous examination or its equivalent, and be engaged during five University years in professional study at a medical college

<sup>10</sup> Statute of the University of Malta, 1915, Government Printing Office, Malta, price 1s.

<sup>11</sup> If obtained after June 25th, 1912, the degree must have been registered in the Presidency.

<sup>12</sup> If obtained after June 1st, 1916, the degree must have been registered in the Presidency.

<sup>13</sup> The Registrar of the University is Mr. K. B. F. M. Dastur, M.A. The Bombay University Calendar (1918) is a volume of 610 pp., printed at the Government Central Press, Bombay.

<sup>9</sup> The Secretary of the Faculty of Medicine is Dr. E. S. Ryerson. The Calendar of the University of Toronto, Faculty of Medicine (1919-20) is a volume of 146 pp., printed by the University of Toronto Press.

recognised by the University. Three examinations are held: the first, or preliminary scientific; the second, or intermediate; and the third, or final; each of them twice in the year. The two former are of the usual character. The final is divided into two parts, which may be taken together two years after the intermediate. Part I. includes medicine, medical jurisprudence, pathology, and hygiene; Part II. surgery, midwifery, and ophthalmology. 203 medical undergraduates passed examinations in 1916. Candidature for the degrees of *B. Hy.*, *M.D.*, *D. Hy.*, or *M.S.* implies that the *M.B.*, *B.S.* degree has been taken not less than a year (*D. Hy.*, 3 years) previously.

*Grant Medical College, Bombay*, was established in 1845, to "impart through a scientific system the benefit of medical instruction to the Natives of Western India," and recognised by the University in 1860. Attached is a laboratory for scientific medical research. The students are arranged in three classes: (1) graduates and undergraduates of the University of Bombay and other recognised Universities who are educated through the English language for medical degrees; (2) members of the European and domiciled European communities who are educated through the English language for the grade of military assistant surgeon; (3) undergraduates and others for the diplomas of the College of Physicians and Surgeons, Bombay. The College has ceased to grant diplomas, and is affiliated to the University for medical education.

#### *University of Calcutta.*<sup>14</sup>

For the degree of *M.B.* the preliminary scientific, first, and final *M.B.* examinations must be passed. The final is divided into two parts, major and minor, which may be taken together. The former includes medicine, surgery, and midwifery; the latter general pathology, medical jurisprudence, and hygiene. An examination for honours is held a week after the pass list is declared. The fees for the three examinations are Rs. 25, Rs. 30, and Rs. 50 respectively. The *M.D.* degree is granted after examination in medicine, pathology, and mental diseases not less than one year subsequent to the *M.B.* The fee is Rs. 100. Degrees of Master of Surgery (*M.S.*) and Obstetrics (*M.O.*) are also granted. A diploma in public health is granted to possessors of the *M.B.* degree or *L.M.S.* diploma by examination after a prescribed course of a year has been carried out. The fee is Rs. 100.

#### *Ceylon Medical College.*

The Ceylon Medical College<sup>15</sup> began in 1870, and the curriculum and examinations were revised in 1901 to accord with modern requirements. In 1888 the licence in medicine and surgery (*L.M.S.*) granted by the College was recognised by the G.M.C. Women were admitted to the College in 1892. There is a medical and an apothecaries' department in the College. A preliminary examination of the standard of the Cambridge Senior Local or School Certificate Examination is required for admission to the five years' medical course. The first professional examination is passed at the end of the first year, the second at the end of the third, and the final in two parts at the end of the fourth and fifth. The fifth year's course includes, besides the usual final subjects, instruction in tropical medicine, skiagraphic demonstrations, and attendance at a leper asylum. The total fees for the medical curriculum, including examinations, amount to Rs. 1223.50. Various Government scholarships and medals are granted.

#### *University of Hong-Kong.*

The Faculty of Medicine of the University of Hong-Kong<sup>16</sup> (1912) had its origin in the work of the Hong-Kong College of Medicine founded in 1887. The School of Anatomy was opened in 1913 and special schools for physiology, pathology, and tropical medicine are in course of erection. The University confers the degrees of *M.B.*, *B.S.*, *M.D.*, and *M.S.* The subjects of the first medical examination are physics, chemistry, and biology; of the second, anatomy, physiology, general pathology (including bacteriology), and elementary pharmacology; of the third, Part I., surgery

and midwifery, Part II., medicine and pathology, including hygiene and tropical medicine. The fee for each part of each examination is \$5, and for conferring the *M.B.*, *B.S.* \$25. The candidate for *M.D.* may present himself in two years and must take general medicine as well as one of the following: State medicine, pathology, midwifery, tropical medicine, physiology. The rules for *M.S.* are similar. The fee for each examination is \$100 and for conferring the degree \$100.

#### *University of Madras.*

A medical school was established in Madras in 1835, which became the Madras Medical College in 1851 and was affiliated to the University in 1877. The College was originally for supplying assistant surgeons and hospital assistants to the army, but now undertakes also the training of students for the medical degrees and diplomas of Madras University. Candidates for the degrees of *M.B.*, *B.S.* must have passed the Intermediate Examination in Arts of the University or its equivalent, and have studied medicine for not less than five years in a college affiliated to the University. Four examinations are held, the third (at the end of the third year) comprising general pathology and hygiene, and the fourth the other professional subjects. The examination fees are Rs. 25, Rs. 25, Rs. 40, and Rs. 50 respectively. The *M.D.* degree may be taken not less than one year after a first-class pass in either medicine, midwifery, pathology, or tropical medicine. The conditions for the *M.S.* degree are similar. The examination fee in each case is Rs. 100. A degree in sanitary science (*B.S.Sc.*) can be taken in two parts one year after the *M.B.*, *B.S.*, the total fee being Rs. 100.

The *Madras Medical College*<sup>17</sup> includes a college department, an apothecary department, a chemists' and druggists' department, and a sanitary inspectors' department. The course of training for the *M.B.*, *B.S.* is charged Rs. 120 a year, or a lump sum of Rs. 540 if paid in advance. Valuable scholarships are awarded by the Government and by the Dufferin Fund, and special Government stipends to women medical students.

#### *Punjab University.*

An examination for the degree of *M.B.*, *B.S.* is held annually in Lahore in May, and consists of three parts—first, second, and final. The first professional examination is open to candidates who not less than two years previously have passed the intermediate examination of the Science Faculty taking the medical student's group; it comprises anatomy, physiology, and materia medica, and the fee is Rs. 30. The second examination is in pathology, forensic medicine, and hygiene, and is taken at the end of the third year; the fee is Rs. 30. The final examination, for which the fee is Rs. 40, is taken at the end of the fifth year and comprises the rest of the professional subjects.

*King Edward Medical College, Lahore*, trains students for the medical degrees and diplomas of Punjab University. The college year consists of one long session of three terms. The course for the *M.B.*, *B.S.* occupies five years, the fees being Rs. 125, Rs. 115, Rs. 135, Rs. 105, and Rs. 105 in successive years. College scholarships are granted.

#### REGISTRABLE FOREIGN MEDICAL DEGREES.

Certain medical diplomas granted in foreign countries also entitle to registration in the foreign list of the Medical Register, provided that the holder is not a British subject or that, being a British subject, the diploma was obtained under domiciliary conditions similar to those attached to colonial diplomas.

*Summary of Registrable Degrees* (the date in parentheses being the year in which Part II. of the Medical Act, 1886, was applied to the country in question).—*Italy* (1901): Degrees of Doctor of Medicine and Surgery of all the Royal Italian Universities. *Japan* (1905): Degrees of Bachelor of Medicine (Igakushi) and Doctor of Medicine (Igaku Hakushi) of the Imperial Universities of Japan; and the Degree of Bachelor of Medicine (Igakushi) of any Government or Prefectural special medical college, or of a private special medical college designated by a Minister of Education of the Empire of Japan. *Belgium* (1915): Degrees of Doctor of Medicine of the Belgian Universities of Brussels, Ghent, Liège, and

<sup>14</sup> The University of Calcutta Regulations (1914) make a volume of 410 pp., published by the University.

<sup>15</sup> The Registrar of the college is Dr. P. J. Kelly. The Ceylon Medical College Calendar (1917-18) is a volume of 91 pp., published by authority and printed by H. M. Richards, acting Government printer, Colombo.

<sup>16</sup> The acting registrar of the University is Mr. K. Brayshaw, B.A. The University Calendar (1918-19) is a volume of 116 pp., printed for the University by Noronha and Co., Government printers, Hong-Kong.

<sup>17</sup> The Calendar of the Medical College, Madras (1918), is a volume of 191 pp., printed by the Superintendent, Government Press, Madras, price 1s.

Louvain, which give legal authority to practise medicine, surgery, and midwifery in Belgium.

#### Italy.

The regulation for the medical diploma is fixed by Royal Decree dated August 9th, 1910, and is the same for each of the 20 universities and institutes where courses of study are arranged. These are in alphabetical order: Bologna, Cagliari (Sardinia), Camerino, Catania, Ferrara, Florence, Genoa, Messina, Modena, Naples, Padua, Palermo, Parma, Pavia, Perugia, Pisa, Rome, Sassari, Siena, and Turin.

The course covers six years, and embraces the following 20 constituent subjects: (1) experimental physics, (2) inorganic and organic chemistry, (3) botany, (4) zoology and comparative anatomy, (5) normal human anatomy (descriptive or systematic, macroscopic and microscopic), (6) physiology, (7) general pathology, (8) pharmacology and toxicology, (9) pathological anatomy and histology, (10) special medical (practical) pathology, (11) special surgical (practical) pathology, (12) medical clinics, general and special, (13) pediatric clinic, (14) surgical clinic, general, special and operative, (15) obstetric and gynaecological clinic, (16) ophthalmological clinic, (17) clinics of nervous and mental diseases, (18) hygiene and public health, (19) legal medicine, (20) dermatological and venereal clinic.

The distribution of these subjects over the six years varies somewhat at the different centres, but the official course at Siena may be taken as an example:—1st year: botany, zoology, normal human anatomy. 2nd year: normal human anatomy, general chemistry, experimental physics, embryology, experimental physiology. 3rd year: normal and topographical human anatomy, experimental physiology, bacteriology, general pathology. 4th year: *materia medica*, special medical and surgical pathology, pathological anatomy, medical and surgical clinic. 5th year: pathological anatomy, medical, surgical, ophthalmological, and dermatological clinic, hygiene and public health. 6th year: medical, surgical, nervous and mental, pediatrics, and obstetric clinic, legal medicine, operations, history of medical science. Twenty-six optional courses in special subjects can be attended by students of various years. The examinations are held in the latter half of October and June.

#### Japan.

The medical course is taken at the Imperial Universities of Kyoto and Tokyo, and at the medical schools of Formosa, Aichi, Chiba, Kanazawa, Kumamoto, Nagasaki, Okayama, and Sendai.

The *Kyoto College of Medicine*<sup>18</sup> was established in 1899. It includes institutes of anatomy, physiology, medical chemistry, pharmacology, pathology, hygiene, forensic medicine, medicine, surgery, ophthalmology, gynaecology, pediatrics, dermatology, oto-rhino-laryngology, orthopaedic surgery, and psychiatry, each in charge of one or more of the 22 professors and 16 assistant professors, the director being Dr. Hayazo Ito. There is a four years' course of instruction, the first year being devoted to anatomy, histology, physiology, medical chemistry, and embryology. In the second year pharmacology, general pathology, pathological anatomy and histology, diagnosis, special medicine, general surgery, and bandaging are added. The first examination is held at the end of the second academic year, the second at the end of the fourth year in surgery, medicine, ophthalmology, gynaecology, and either hygiene or forensic medicine (the choice being determined by lot). At request students are also examined in pediatrics, dermatology, oto-rhino-laryngology, psychiatry, and orthopaedic surgery. In the year 1910-84 students graduated in medicine from the College.

#### Belgium.

The medical course for the degree of M.D. may be taken at any of the four Universities: Free University of Brussels, State University of Ghent, University of Liège, Catholic University of Louvain. After a preliminary year and an examination which may be taken in two parts—(1) logic, zoology, botany; (2) physics, chemistry, geology—the student becomes “*candidat en sciences naturelles*.” Two years are then devoted to the ancillary sciences, the examination again being in two parts—(1) embryology, systematic

anatomy Part I., histology, comparative anatomy, physiology; (2) systematic anatomy Part II., regional anatomy, special histology, psychology, special physiology—when the stage of “*candidat en médecine*” is reached. Professional studies occupy three years at least, and there are three further examinations. The first includes (i.) general pathology and therapeutics; (ii.) elements of pharmacology and pharmacodynamics; (iii.) pathological anatomy; (iv.) general surgical pathology. The second includes: (i.) medical pathology and special therapeutics, including mental diseases; (ii.) special surgical pathology; (iii.) public and private hygiene; (iv.) the theory of accouchement. The third and final comprises (i.) legal medicine, (ii.) medical clinic, (iii.) surgical clinic, (iv.) operations, (v.) ophthalmological clinic, (vi.) obstetric clinic, as well as practical tests in pathological microscopy and regional anatomy.

The Universities of Ghent and Liège grant a diploma of “*médecin-hygiéniste*” after examination to medical graduates of at least one year's standing.

*University of Liège.*—The Faculty of Medicine includes 15 professors and eight lecturers. The dean is Professor L. Fredericq (Institut physiologique). The fee for inscription in the medical faculty is Fr. 200 for the grade of candidate and Fr. 200 for each of the three parts of the professional examination. Details of the courses may be obtained from Professor Ch. Jolin, secretary to the medical faculty.

*University of Louvain.*—All the courses in the Faculty of Medicine have been resumed. For the third professional examination the programme is as follows: A. Lemaire (medical clinic), R. Schoekaert (theory of accouchement), A. Vander Straeten (ophthalmological clinic), R. Bruynoghe (legal medicine), G. Debaisieux (surgical clinic), L. Van den Wildenberg (oto-rhino-laryngological clinic), A. Van Mosseken (dental clinic), O. De Mees (minor surgery). The dean of the faculty is Professor Schoekaert, and the secretary Professor Bruynoghe (rue Marie Thérèse 100). An “*Année Académique, 1919*,” has been issued from the University press.

*University of Brussels.*—The former courses in the Faculty of Medicine were resumed (see THE LANCET, March 1st, 1919, p. 353) on Jan. 22nd last, as well as the clinics at St. Jean and St. Pierre, and the instruction for the diploma of public health.

Details of these courses may be obtained from the secretary of the University at rue des Sols 14, Brussels.

#### THE M.D. BRUSSELS FOR STRANGERS.

The examination is arranged in three parts. No conditions of residence are needed; the time required for the three examinations seldom exceeds 10 or 12 days, and candidates who are unable to be so long away from home may take each part separately. The examinations are conducted in English through the medium of an interpreter (without additional charge). They take place on the first Tuesday in November, December, March, and May, and the second Tuesday in June. They are *viva voce*, but candidates may have a written examination by paying an additional fee of £1 for each test. This does not exempt them from the *viva voce* examination. Part I. includes general medicine; *materia medica* and pharmacology; general surgery; and the theory of midwifery. Part II. includes general therapeutics; pathology and morbid anatomy, and the use of the microscope; special therapeutics and medicine of internal diseases; special surgery; and mental diseases. Part III. includes public and private hygiene; medical jurisprudence; clinical medicine; clinical surgery; examination in operative surgery, consisting of some of the usual operations on the dead subject—viz., amputation, ligation of artery, &c.; ophthalmology; examination in midwifery, consisting of obstetrical operation on the mannequin (model of pelvis), examination in regional anatomy with dissection; and bacteriology.

DONATIONS AND BEQUESTS.—Under the will of the late Mrs. M. L. Burns, Mr. Pierpont Morgan's sister, the testatrix has bequeathed £5000 to Guy's Hospital.—The late Mr. James Stephenson Binning has left by will £1000 for such London hospitals as the executors may select.—The late Mrs. Paris has bequeathed £1000 to the Totnes Cottage Hospital in memory of her late sister, Miss F. Mitchell.

<sup>18</sup> The Kyoto Imperial University Calendar (1911) is a volume of 164 pp., published by the University.

## Obituary.

AUGUSTUS G. VERNON-HARCOURT, F.R.S.,  
LATE PRESIDENT OF THE CHEMICAL SOCIETY.

Professor A. G. Vernon-Harcourt, whose death was announced early this week, was a well-known figure at the University of Oxford, where he was Lees Reader in Chemistry and attached to Christ Church. He retired from this appointment some 20 years ago, after a long record of chemical research whose outcome was of a highly valuable nature. His first studies referred to the rate at which chemical change proceeds between given substances, the simple one chosen for the purpose being that occurring between hydrogen iodide and hydrogen peroxide, iodine being evolved. He eventually demonstrated that the rate of chemical change was strictly proportional to the mass of the interacting substances concerned. An insight into the law of mass action was thus gained, and this work was followed up by other investigations, which led to results of great theoretical importance. They were of practical importance also, as in certain cases they enabled the achievement of the laboratory to be carried to the factory. This work was begun at Oxford in the early "sixties." Later on Vernon-Harcourt turned his attention to the purification and testing of coal-gas, and he evolved an ingenious method of eliminating certain sulphur compounds from this illuminant. His process for estimating the sulphur in coal-gas is in use at the present day. During this work he invented the well-known pentane lamp as the official standard of illumination, replacing the doubtful standard of a wax candle. In medical science Vernon-Harcourt's name will be remembered in connexion with a chloroform dosimetric inhaler which he devised. This apparatus enabled the anaesthetist to control the composition of the mixture of air and chloroform passing to the patient. The Chloroform Committee of the British Medical Association accepted this apparatus as satisfactory, but clinical authorities were not long in pointing out its disadvantages, maintaining that chloroform accidents cannot be entirely prevented by regulating chloroform percentages. The inhaler, however, proved useful when provided with an oxygen attachment in cases in which a light anaesthesia was required. The risk of using a dosimetric inhaler was that while it suggested security it might divert the attention of the chloroformist from his patient's condition. The apparatus was most ingeniously designed and succeeded in giving exact proportions of chloroform and air up to a maximum of 2 per cent. of the anaesthetic. Vernon-Harcourt's researches gained for him the Fellowship of the Royal Society in 1868, and he was elected President of the Chemical Society in 1895. He died on August 23rd in his 85th year at his residence near Ryde in the Isle of Wight.

**THE OXFORD ROLL OF SERVICE.**—A final and enlarged edition of the Roll of Service of the University of Oxford is now in preparation. Forms asking for information have been sent to all members of the University, past or present, who are known to have been on military or naval service, and whose addresses could be obtained. Those who have not received the forms should send full information of their service either to the "Compiler of the Roll of Service" at their old College, or to E. S. Craig, Esq., Assistant Registrar, University of Oxford. All such information should be sent in before Sept. 15th.

## URBAN VITAL STATISTICS.

(Week ended August 23rd, 1919.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 9.7, 9.7, and 10.0 in the three preceding weeks, was again 10.0 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 10.4, and was the same as that recorded in the previous week, while among the remaining towns the rates ranged from 2.8 in Ilford, 4.4 in Northampton, 5.0 in Wallasey, and 5.2 in Bournemouth, to 16.2 in Middlesbrough, 16.4 in Newcastle-on-Tyne, 17.2 in Hastings, and 19.0 in Tynemouth. The principal epidemic diseases caused 263 deaths, which corresponded to an annual rate of 0.8 per 1000, and included 155 from infantile diarrhoea, 44 from measles, 41 from diphtheria, 12 from whooping-cough, 9 from scarlet fever, 5 from enteric fever, and 2 from small-pox. Measles caused a death-rate of 1.2 in Newcastle-on-Tyne, 1.3 in Gateshead, and 1.8 in Tynemouth, and scarlet fever of 1.9 in Wigan. There were 1464 cases of scarlet fever and 1063 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1517 and 1112 respectively at the end of the previous week. The causes of 26 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham and 2 each in Liverpool, Manchester, Salford, and Newcastle-on-Tyne.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 10.6, 10.0, and 9.9 in the three preceding weeks, rose last week to 10.7 per 1000. The 243 deaths in Glasgow corresponded to an annual rate of 11.3 per 1000, and included 28 from infantile diarrhoea, 4 from measles, and 1 from whooping-cough. The 72 deaths in Edinburgh were equal to a rate of 11.2 per 1000, and included 2 from measles and 2 from diphtheria.

**Irish Towns.**—The 124 deaths in Dublin corresponded to an annual rate of 16.0 per 1000, and included 26 from infantile diarrhoea. The 130 deaths in Belfast were equal to a rate of 16.9 per 1000, and included 16 from infantile diarrhoea, 1 from scarlet fever, and 1 from diphtheria.

## Medical Diary for the ensuing Week.

**LECTURES, ADDRESSES, DEMONSTRATIONS, &c.**  
LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton:—

MONDAY, Sept. 1st.—4.30 P.M., Lecture XI.:—Ætiology—Symptoms. Complications and Treatment of Duodenal Ulcer.

FRIDAY.—4.30 P.M., Lecture X.:—Congenital and Acquired Pyloric Stenosis.

## Births, Marriages, and Deaths.

### MARRIAGES.

**POWELL—RICKETTS.**—On August 21st, at St. Barnabas Church, Pimlico-road, S.W., Mr. L. K. M. Powell, 19th Bengal Lancers, son of the late Henry Watson Powell, of the Mercers' Company and Australia, to Beryl, only daughter of the late T. F. Ricketts, M.B., F.R.C.S., and Mrs. Ricketts.

**SMITH—ELLIS.**—On August 26th, at Phillack Parish Church, Cornwall, Matthew Baird Smith, B.Sc. M.B., Ch.B., to Alice May, daughter of Christopher Ellis, Hayle, Cornwall.

**TASKER—ROBINSON.**—On August 21st, at Woudham Parish Church, H. L. Tasker, M.D., of 58, New Cavendish-street, W. 1, son of the Rev. W. Lindley Tasker, to Adela Mary, eldest daughter of Mr. and Mrs. J. Robinson, of Ring's Hill, Borsdal.

## Chadwick Lectures

ON

## THE PROBLEM OF HYGIENE IN EGYPT.

*Being Three Lectures delivered at the Summer Session, 1919,*

BY ANDREW BALFOUR, C.B., C.M.G., M.D.,

DIRECTOR-IN-CHIEF, WELLOOME BUREAU OF SCIENTIFIC RESEARCH;  
LATE PRESIDENT, EGYPTIAN PUBLIC HEALTH COMMISSION.

## LECTURE I.—THE CAUSES OF THE PROBLEM.

MR. PRESIDENT AND GENTLEMEN,—Egypt is the hub of the wheel of Empire. The importance of that ancient land is fully recognised from a military, political, and commercial standpoint. It has bulked largely in the world's history, and recent events have certainly not tended to diminish its status in those directions. It is, however, doubtful if, in this country at least, the significance of Egypt from a hygienic point of view is equally realised. And yet in what may be called "imperial medicine," Egypt must ever play an increasingly important rôle.

## EGYPT AS AN INTERNATIONAL FILTER.

She lies at the gateway to the East, the Suez Canal traverses her territory, she acts as a great filter, a filter for disease. This filter, however, differs markedly from others with which we are acquainted, for the filtration it effects is a double one. It protects Europe from such diseases as plague and cholera, ship-borne from India, Mesopotamia, Arabia, and ports on the western Red Sea littoral, and it guards these countries and places from the risk of infection coming from southern Russia, the Levant, and various foci in the Mediterranean. In days to come there will be few more important quarantine stations than Suez, while Port Said and Alexandria keep watch and guard on vessels hailing from north and east and west.

Although a constant vigilance has to be exercised, no great strain is imposed upon those responsible, save at the time of the Mecca pilgrimage, when the migrations of the faithful occasion the utmost alertness. More especially is this the case when the pilgrimage is declared "brut" or infected. The term "brut" is a French word which has various meanings, such as rough, raw, crude, and so forth. It also signifies "void of reason," and seems almost to have been adopted on account of this meaning, for there is nothing about it to denote infection. In all probability it was employed merely as a convenient term, the antithesis of the French "net," and one with which the pilgrimage could be discreetly labelled, even if infection was merely suspected, not absolutely proved. When such a label was affixed the problem became one of much anxiety. Picture to yourselves the conditions of the Hedjaz. Vast throngs of people, often ill-fed and ill-clad, crowded together at such a pestilential port as Jeddah, an assemblage polyglot in the extreme and hailing from every quarter of the Moslem world, a concourse in some respects clearly in its habits, thanks to the Mohammedan ritual, but ignorant of every law of modern hygiene, a great gathering which, having completed its devotions at the Prophet's shrine, was intent on one thing only—to return home as quickly, cheaply, and easily as possible.

*Pilgrims by Road, Rail, and Sea.*

While this was true of the majority, it is interesting to note that, owing to the difficulties of travel in the Hedjaz in pre-war days, many pilgrims after travelling by the railway to Medina, actually made for Egypt and then started off for Mecca, a curious roundabout way of attaining their goal, and one which introduced fresh sanitary complications. In any case, the crowded port was followed by crowded steamers whereon the pilgrims were packed almost like tinned sardines, for the voyage is short and the restrictions are none too stringent. Amongst this mass of humanity sweltering in the heat of the Red Sea plague or cholera might make its appearance and begin to claim its victims. The ship is then infected and is a danger to Egypt—a problem to be solved. Yet, again, she may merely hail from an infected port and require watching for a certain period—a different proposition.

But all pilgrims did not reach Egypt by the southern sea route. You are familiar with the Hedjaz railway, which has

played so notable a part in the war. Formerly it played an equally important rôle as regards the Mecca pilgrimage and the trains were, at the time of the Haj, thronged with a multitude travelling, as Clemow has described, in open trucks or luggage vans. Amongst them were Egyptians, who often chose this route for their return journey and eventually reach the sea at Jaffa, Haifa or Beyrout, whence they took ship to Egypt, avoiding to some extent the restrictions placed upon those travelling via the Red Sea. (See map.)

So much for the rôle of Egypt as an international filter. The measures taken to deal with the problem of sea quarantine will be considered in due course, but it must be remembered that the war has introduced a new factor into the sanitary problem arising out of the relation of Egypt to her neighbours. This new factor is the railway linking the Nilotic territories with Palestine. Prior to the war the question of land quarantine was one of little importance. To the west lay Tripoli, separated from the populous lands of the Delta by a great desert, which was seamed only by caravan routes and uninhabited save by wandering Bedouins and where scattered oases afforded water and means of life. In the south Egypt merged with the Sudan, and there was more danger of the latter being infected from Egypt by way of the Nile than there was of Egypt being infected from the Sudan. Eastwards lay the desert of the Sinai Peninsula, an effective barrier between the Suez Canal and Syria.

Now, as by the stroke of an enchanter's wand, all is changed so far as this eastern frontier is concerned. An iron link has been forged, a link potent for good and evil, and in a few hours the traveller passes from the sands of Egypt to the mountains of Judea. It is conceivable that in the near future yet a third form of quarantine may have to be instituted, as there is every likelihood of Egypt becoming a halting-place for great airships en route from India to Europe.

Interesting as are these questions of aerial, land, and maritime quarantine, it must be understood that the main problem of hygiene in Egypt centres in the internal condition of the country.

## MEDIÆVAL SANITARY CONDITIONS.

In the first place, it is necessary to remember that, so far as the great mass of the native population goes, sanitary conditions may be described as mediæval. In the second place, one must not forget that all that really counts in the Egypt of to-day is artificial. The country as we know it is the product of man's activity. Egypt is so very old that it is difficult to get beyond a period when man was not busy modifying it to suit his needs, but doubtless at the beginning the land was one huge desert with fertile strips bordering the Nile, strips dependent on the annual rise and fall of the great river. Then came man and harnessed the water to his uses. While, owing chiefly to the configuration of the land, he has not created any great change in Upper Egypt, he has established the green Delta with which we are now familiar, a Delta which in many respects is a hot-bed of disease. Irrigation, while conferring the greatest benefits on the land of the Pharaohs, while in reality creating modern Egypt, has been by no means an unmixed blessing, for closely associated with it are the two great worm diseases, ankylostomiasis and schistosomiasis (bilharziasis), which have produced such dire effects upon the fellahen.

Considerations of climate enter little into the problem of hygiene in Egypt, for such influence as the climate exerts is largely of a beneficial nature, though it should be noted that the climatic conditions at certain seasons of the year are singularly favourable to the propagation of flies, and hence to the dissemination of such diseases as enteric fever and dysentery.

*The Racial Factor in the Health Problem.*

The race, and more especially those fellahen of whom we have spoken, constitutes a very important factor in the health problem. Who are these brown-faced, blue-garbed sons of the soil? They constitute the immense majority of the population; they form the lowest stratum of the social organisation of the country; they are the descendants of those who, until Great Britain undertook the work of reformation in Egypt, were beaten and robbed, the prey of pashas and of usurers. Physically they are a sturdy race, and, as Lord Cromer has stated, when left to themselves, kindly and even jovial. These characteristics are more marked in the people of the Delta, those of Upper Egypt being somewhat

truculent and less easy to handle. Unhappily, from a hygienic standpoint, the fellahen are also steeped in ignorance and superstition, void of initiative, with no outlook, with little ambition, content with the daily round of labour in the fields, and in many cases doomed to suffer much misery from preventable disease. As a recent Commission has said, and truly said: "To-day the greater part of Egypt is filthy and no self-respecting populace can be raised in filthy surroundings. As of old, Egypt is plagued by disease, and it is hopeless to expect a disease-ridden people to play their proper part in furthering the welfare of their country. The infant mortality of Egypt is appalling, actually one-third of the children born dying in infancy. The verminous condition of the fellahen shows no improvement, though lice are now known to be conveyers of typhus and relapsing fevers which account for so many deaths." And, again, when speaking of the necessity for education and for improvement in village sanitation, it is stated that "the healthy fellah is happy and content because he has never

#### *Archaic Methods of Midwifery.*

Dr. Elgood has pointed out that there must be at least 4,000,000 women in Egypt of child-bearing age. The general methods of midwifery she describes as archaic and brutal. No one knows how much puerperal fever occurs, but, taking Cairo alone, it is significant how many funeral biers are seen in the streets with silver bridal tresses adorning their head-pieces, the sign that a woman has died during her first year of married life. In any case, there can be no doubt that, apart from other ailments, the majority of lower-class Egyptian women suffer from uterine and ovarian complaints. Gonorrhœa is exceedingly common, syphilis far from rare, while the mental effect produced by the frequent loss of children must tend to depress vitality and induce apathy and despair. The harem system makes the problem of succouring these women difficult, though not hopeless. Naturally enough, they and their husbands object to male assistance, and, even at out-patient clinics, to the presence

known anything better, while the unhealthy fellah is far from being happy and content, though he is, perhaps, the most patient of sufferers."

It is, indeed, this quality of patience, an almost bovine patience, which is one of the chief features in the character of the fellahen, but, so far as disease goes, there is a kind of hopelessness about it which is pathetic. Especially is this true of the women, who, in contrast to the men, wear black garments. Now black is the colour of mourning, and well may it be worn by the women of the fellahen, for their lot, from a medical and sanitary standpoint, is too often a sad and weary one. I propose to consider the problem of the women first, for in eastern countries questions of health are very intimately bound up with the state of the female population. Unhappily, the poorer women of Egypt, be they fellahen or town dwellers, have not lacked champions in the past. Their most energetic and scientific supporter of late years has been Mrs. Elgood, a woman doctor who has laboured incessantly to improve their lot, and who, as medical officer to the Ministry of Education, has also fought the battle of the children.

of male students or of "tamurgis," as the male hospital orderlies are called.

According to Dr. Elgood, the absence in most Government hospitals of a European matron or a woman doctor prevents the lower-class men entrusting their women to the care of such institutions. Another condition which leads to difficulties is the treatment of prostitutes in Government hospitals. So long as this class is admitted to the same building as the honourable women, so long will the latter object to being treated there, even though the prostitutes are housed in special wards.

Lastly, there is the question of hospital fees. Small though these are, they are prohibitive, for many of the working-class Egyptians are miserably poor. There is a rule that the very poor shall not be charged, but nearly all who attend hospital are in this state, for it is the last resort of the destitute. At the present time most of the maternity assistance in Egypt is rendered by dayas or midwives, poorly trained women of a low and dirty class, who are responsible for many of the deaths both of mothers and infants. In addition a certain number of hakimas or, as they

are more usually termed, *mumarridas*, exist, to whom further reference will be made when we consider the solving of this part of the Egyptian health problem.

*Effect of the Mothers' Disabilities on the Child Population.*

Healthy children are a nation's greatest asset, but how can the poorer Egyptian children be healthy when their mothers labour under the disabilities we have just considered, and are in addition dirty and ignorant? A third of them die as infants. Those who survive, especially if in the large towns, have a struggle for existence. A great number attain adolescence exhibiting some defect. Many harbour ankylostomes or schistosomes, or both, and suffer grievously in consequence. A large percentage are infected with other helminths, many have damaged eyes, some are cripples, others have splenomegaly, often combined with hepatic cirrhosis. Yet others acquire pellagra. Not a few are disfigured by small-pox, and probably a minority become healthy men and women. Yet there is no instruction in diseases of infants and children at the Kasr-el-Aini School of Medicine, the only institution in Egypt granting diplomas to practise the healing art, and the facilities for the gratuitous treatment of infants and children are woefully inadequate, save possibly where eye diseases are concerned.

*How the Fellaheen Live.*

We have digressed a little from the subject of the fellaheen, but, returning to them again, let us see how they live and labour and what ideas they possess as regards the cure and prevention of disease. They inhabit villages which, though often picturesque, transgress wellnigh every law of health; congeries of flat-roofed, ill-ventilated, mud dwellings, some of them partly underground, crowded like rabbit warrens, and where the houses are shared alike by man and his domestic animals—donkeys, cattle, buffaloes, sheep, goats, cats, dogs, rabbits, fowls, and pigeons. The roofs are usually piled high with grass or rubbish, and commonly serve as latrines for the women of the household. The lanes or passages between the houses are narrow, often tortuous, and not infrequently blocked by stacks of manure. There are many blind alleys. There is no sweep of purifying air. No sanitary conveniences of any kind exist, but rats swarm, and at certain periods there is a plague of flies. Hard by there is often a birka or pool which may serve as a mosquito nursery, and the water of which, frequently used for drinking purposes, is generally grossly polluted. It may harbour the infected snail hosts of the schistosomes and be a danger to those bathing in it. The usual source of water-supply is a canal into which all manner of filth finds its way and in which buffaloes love to soak themselves.

The larger villages, if judged by the number of their inhabitants, might well be regarded as considerable towns, and may contain better-class houses in which the wealthier landowners live. Most of the fellaheen, however, are small proprietors subsisting on the produce of their fields. Apart from the presence of disease and deformities, their lot under British rule is by no means a hard one, and certainly compares favourably with that of the poor of the congested towns, into which the rural population tends to flock, thereby creating one of the most serious of the sanitary problems that have to be faced. There is no room for the newcomers, adequate building schemes to cope with the difficulty are non-existent, and the result is overcrowding with all its attendant ills, evils accentuated in a land where the lower orders are infested by vermin, and where the plague-carrying rat flea abounds.

One has no wish to paint too gloomy a picture of Egyptian life. There is much in it that is cheerful and attractive, at least in the country districts. The ravages of disease are not very apparent to the casual observer. It is true he cannot fail to be struck by the number of blind persons or unfortunates with defective vision; he may notice that deformities are common, and occasionally be shocked by the sight of a wretched leper, but otherwise he would probably regard the populace as strong and well-liking. It is not until one studies statistics, visits the dispensaries and hospitals, becomes familiar with the asylums and homes for incurables, inspects the slums of the great cities, and is brought into contact with epidemics that one appreciates how great a burden of suffering and inefficiency is borne by the populace of Egypt, and how much of this burden is preventable. Take the work of the fellaheen, work with the primitive plough and the fass (hoe or spade) in the irrigated

fields, work which entails walking or standing ankle- and knee-deep in the alluvial mud. Owing solely to the pollution of the soil with human excrement, there is an ever-present risk of infection with the larvæ of ankylostomes, resulting in that hookworm disease of which, thanks to the Rockefeller Institute and its campaign, we have heard so much of late years.

*Abysmal Ignorance and its Results.*

Again, either in the course of his work or when bathing or washing or drinking, the fellah is often brought into contact with water which, owing to pollution with urine or fæces, is charged with the cercariæ of one or other of the human schistosomes, and in many cases he falls a victim to schistosomiasis. Both schistosomiasis and ankylostomiasis are serious diseases which can be prevented by suitable hygienic measures, and the same is true of many others. It is easy to proclaim this fact, but to tackle preventable diseases properly it is highly desirable to enlist the sympathy and support of the populace who suffer from its effects. Such is no easy task even amongst an educated community. The native Egyptian, however, is still plunged in abysmal ignorance as regards the nature and cure of disease. Lord Cromer in his book, "Modern Egypt," quoting from an interesting paper written by the late Dr. Sandwith in 1884, cites several instances of strange superstitions which showed that the medical knowledge amongst the poorer classes was not materially in advance of that current in the days of the Pharaohs. Here is one not quoted, but culled from the same authority. Numerous alleged cures exist for ophthalmia, "such as wearing a red bead or gold ornament on the forehead or rowing across the Nile at Cairo to deposit a lump of mud on the further shore. During the process of some of these cures it is considered most important that the eyes should not be washed for 40 days, and it is not uncommon to see children with both eyes completely covered with a dry scab which the parents refuse to have removed, although pus may be streaming down the child's cheeks."

It is to be feared that in the thirty odd years which have elapsed since Dr. Sandwith collected these curious beliefs there has been no very great change, though, doubtless, there has been some lessening in this ignorance and credulity, for the leaven of education has been at work, new ideas are abroad, and the doctor is more trusted than he used to be.

THE CONDITIONS IN URBAN AREAS.

Hitherto we have been considering chiefly the rural districts and the fellaheen. Let us take a look at the urban populations and at the conditions which exist in such great cities as Cairo and Alexandria. I cannot do better than quote Lord Cromer's vivid description of the first ten people a visitor to Cairo may happen to meet in the streets of "that maze of old ruin and modern café, that dying Mecca and still-born Rue de Rivoli," as it was christened by Sir William Butler.

"The first passer-by is manifestly an Egyptian fellah who has come into the city to sell his garden produce. The headgear, dress, and aquiline nose of the second render it easy to recognise a Bedouin who is, perhaps, come to Cairo to buy ammunition for his flint-lock gun, but who is ill at ease amidst urban surroundings, and will hasten to return to the more congenial air of the desert. The small, thick-lipped man with dreamy eyes, who has a far-away look of one of the bas-reliefs on an ancient Egyptian tomb, but who Champollion and other savants tell us is not the lineal descendant of the ancient Egyptians, is presumably a Coptic clerk in some Government office. The face, which peers somewhat loweringly over a heavy moustache from the window of a passing hrougham, is probably that of some Turco-Egyptian Pasha. The man with a bold, handsome, cruel face, who swaggers by in long boots and baggy trousers, must surely be a Circassian. The Syrian money-lender, who comes next, will get out of his way, albeit he may be about to sell up the Circassian's property the next day to recover a loan of which the capital and interest at any ordinary rate have been already paid twenty times over. The green turban, dignified mien, and slow gait of the seventh passer-by denote some pious Sheikh perhaps on his way to the famous University of El-Azhar. The eighth must be a Jew, who has just returned from a tour in Asia Minor with a stock of embroideries, which he is about to sell to the winter tourists. The ninth would seem to be some Levantine nondescript, whose ethnological status defies diagnosis; and the tenth, though not easily distinguishable from the latter class, is in reality one of the petty traders of whom Greece is so prolific, and who are to be found dotted all over the Ottoman dominions. Nor is the list yet exhausted. Armenians, Tunisians, Algerians, Soudanese, Maltese, half-breeds of every description, and pure-blooded Europeans pass by in procession, and all go to swell the mass, if not of Egyptians, at all events of dwellers in Egypt."

Naturally this mixture of races adds to the difficulties of the sanitarian, which have been further enhanced by the existence of the capitulations. These were at first really

concessions or privileges granted by Turkey to foreigners resident in Egypt, but under the lax rule of the Khedives the privileges grew into abuses, multiplied in various directions, and became a curse to the country and a great bar to sanitary reform, because many of those who offended against the public health could not be brought to book. Happily, the capitulations are now on their last legs, but they have wrought untold harm for many years. This is why in Cairo so many of the so-called *établissements insalubres*, really offensive trades, thoroughly deserve their title; this is one reason why it has been so difficult to deal with the mosquito pest; this has been one of the causes which have wellnigh broken the heart of the energetic medical officer of health in his struggle to abate nuisances and secure convictions.

But the capitulations are by no means the sole reason why Cairo has a high death-rate and in many parts is insanitary in the extreme. In 1911 in a well-known medical work there appeared the following criticism which gave rise to much heart-burning in certain quarters. After commenting on the cesspools, the mosquitoes, the sewage-sodden soil, and the vermin of the Egyptian capital, the writer goes on to say:—

"The human mortality is enormous, especially the infantile mortality. The figures supplied by the Public Health Department are unreliable (as I know, for I have assisted to compile some of them). The actual population is unknown, many deaths are probably never reported, and sickness is not usually notified. All deaths are supposed to be registered, the diagnosis usually being made by a brief inspection of the dead body. Doctors will not notify disease because they say that it ruins their practice. Landlords prefer to knock holes in the sides of their cesspools and allow the sewage to flood their cellars and basements rather than go to the expense of having them pumped out. The water-supply is not the best obtainable, the streets are not properly cleaned, and enormous heaps of dung and rubbish have been allowed to accumulate for years past on the outskirts of the city. Many of the streets are not metalled; which perhaps is a good thing, for the rough surface acts as a sponge for the stale urine which would otherwise collect in puddles. Dung and street refuse are used as fuel generally; and large collections of this rubbish are kept for this purpose on the roofs of the 'Turkish baths.' Nearly all the dogs have been destroyed owing to outbreaks of rabies, and many cats have taken their place as natural scavengers. Hordes of flies, which breed in the dung and rubbish, abound everywhere, and are nearly as great a nuisance as the mosquitoes. Without exaggeration, Cairo may be described as a city which is hardly fit for habitation, and at present it must rank with Moscow, Peking and Hankow as being one of the most insanitary spots in the world.

Happily there has been in some directions a considerable change; or the better since the above appeared.

#### *Insanitary Old Cairo.*

I myself recall an incident which opened my eyes as to the insanitary state of affairs permitted to exist in a city the European part of which almost merits the old title of Cairo the Magnificent, so far as spacious streets and fine buildings are concerned. A certain Sewage Transport Company approached me with a view to obtaining a concession for dealing with the conservancy of Khartoum. I met the company's representatives in a very ramshackle and decayed building in Old Cairo. As is usual in Egypt, coffee was served, and on finishing my cup I discovered amongst the syrup at the bottom of it a dead fly. I fear this prejudiced the company's application from the outset; but in any case it could never have been entertained, for the ideas advanced were, to say the least, unprogressive, and the methods of working in Cairo were disgraceful. Pail contents were collected in those insanitary juggernauts called Crowley carts, which jolted and splashed along the unpaved, badly kept roads, to the joy of thousands of flies which bore them company. The cart contents were dumped into shallow open depressions in the soil no great distance from the city confines, and were there mixed with material dug from the neighbouring gebels, which is said to have fertilising properties. The nauseous mixture, after drying in some measure, was spread out on the top of these same gebels for further desiccation. Naturally it pulverised and naturally the south wind wafted it down upon the city. Is it possible to imagine a more filthy and insanitary procedure? Is it strange that sore throats are frequent in this city of dust and smells? These methods are still in vogue, for the great drainage scheme has not yet touched Old Cairo, and though there is better supervision the conditions remain very unsatisfactory. One has only to read the report of the Sanitary Commissioner sent out by THE LANCET in 1908 to realise how necessary it was, and still is, to cleanse the Augean stable. He paints a lurid picture of the rubbish heaps to the north of the city, and though things have improved in some measure, a good deal yet remains to be

done. Elsewhere, amongst the tangle of narrow streets in the Bulaq, Saïda Zeinab, and Bab-el-Sharia quarters all manner of insanitary conditions continue to flourish. The meat market is very far from ideal, the tripe market an abomination. Many of the cowsheds and dairies are filthy in the extreme. The roofs of the houses are used as latrines, the condition of the wells in their basements is enough to suggest cholera. Filth and flies, overcrowding, vermin, infected food and drink, stagnant air, disease and destitution, all are there. Is it any wonder the Sphinx sits yonder in the desert and gazes with stony and sardonic smile over a city with a death-rate of nearly 40 per 1000 per annum?

#### *The Same Evils in Modern Alexandria.*

But you will say, after all Cairo is a great and ancient native city, an eastern city, and we know what happens to the man who tries to hustle the East. Let us then take train to Alexandria, which is largely a European city, a proud and prosperous city with a municipality and, *mirabile dictu*, wellnigh as fine a slaughter-house as is to be found anywhere in Europe. Here, however, are the same evils—slum quarters or *echèches* of the worst description, centres of typhus and relapsing fever, often cheek by jowl with better-class dwellings, often close to areas inhabited by well-to-do Europeans. The conditions at the hammams, or Turkish baths, are scandalous, for at these places the town refuse, often ill-smelling and foul, is used as fuel, and, being stored anyhow and everywhere, is most offensive and dangerous. It breeds flies galore, it affords a happy hunting-ground for lean donkeys, greedy goats, and mangy cats. The creatures who handle it look like soot-besmirched myrmidons of Satan, and, strange to say, in the furnaces which it feeds beans are baked in earthenware jars from which they are sold in the neighbouring streets.

Until the sanitary authorities of the Expeditionary Force took stringent action most of the aerated water factories, the bakeries, pâtisseries, ice-cream shops, and the kitchens of the restaurants were sources of danger to the community, and in certain instances disgusting as well as dangerous. The markets leave much to be desired, the municipal arrangements for refuse destruction are totally inadequate, the methods of disposal of latrine-bucket contents and sewage sludge at Mex and Gabriel offensive and noxious, the Infectious Diseases Hospital a disgrace to a city like Alexandria, and the municipal bacteriological laboratory a place in which it is a crying shame to ask any scientist to work—at least during the hot, moist summer.

It is the same more or less in all the towns of Egypt. Here and there, as at Suez and Port Said, good work by energetic officials has remedied matters in some degree, but not so very long ago I encountered amongst the mounds of rubbish awaiting incineration at Port Said the most remarkable and nauseating odour it has ever been my ill fortune to experience, and I may say I am somewhat blasé as regards insanitary effluvia. It had a peculiar sweet flavour which defies description and demanded instant flight, so that I am still wondering what could possibly have produced it.

#### THE PRINCIPAL INFECTIVE DISEASES.

Now, what are the principal diseases which form the natural corollary to this state of affairs in the Egypt of to-day—the Egypt, remember, over which this country has cast her mantle of protection, which has a rightful claim upon us for assistance and advice in safeguarding the health of her people, which, if her sanitary salvation is to be secured, must be guided wisely and well along the paths of hygiene?

I have already spoken of the two great worm diseases, reference has been made to the frequency of other helminthic disorders, typhus and relapsing fever have been mentioned, allusion has been made to enteric fever, dysentery, plague, cholera, small-pox, pellagra, leprosy, splenomegaly, idiopathic hepatic cirrhosis, and ophthalmia. There has been some reference to venereal complaints, to deformities, and to gynaecological disorders, but we are by no means at the end of the list. Before proceeding, however, a few words may be said about one or two of those just cited. Dysentery amongst the native Egyptians, when not a symptom of rectal bilharziasis, is chiefly of the amœbic type. Whether bacillary or amœbic, it is a filth disease the cause of which, like those of enteric, may be summarised as careless contact cases, carriers—chiefly cooks—drains, dairies, dirty drinking-water, the dust of dried dejecta, and the repulsive regurgitation, dangerous droppings and filthy feet of fecal-feeding

flics fouling food. Plague, at least in its bubonic form, is due to vermin, cholera in the main to polluted drinking water, and the way in which cholera is held in check is a fine tribute to the work of the Department of Epidemic Services. Small-pox has few terrors for the vaccinated, and yet it is sad to see its ravages in Egypt. Pellagra is still a puzzle, but is possibly a combination of a food deficiency disease and an auto-intoxication from the bowel. Anyway, it helps to fill the asylums and causes considerable misery and distress. Leprosy, another enigma, so far as its method of spread is concerned, is certainly associated with dirt and destitution, and is by no means a stranger to some parts of Egypt. Yet nothing is done for it, and the leper is free to infect the healthy.

Splenomegaly, often accompanied by cirrhosis of the liver, may be due to various causes, all of which are not yet fully understood, but some of which are assuredly of an insanitary nature; while ophthalmia, in all its various and disfiguring forms, is too often directly traceable to lack of the elements of hygiene and to the ubiquitous fly. Is it not a terrible thought that at the time of the last Census it was found that more than half a million persons in Egypt were blind in one or both eyes! All this is a sorry tale, whether or not we believe man is made in God's image, but there is more to tell. Dengue fever, now definitely known to be mosquito-borne, occurs every now and then in Cairo and elsewhere, malaria still lingers near Ismailia, and is by no means infrequent along the Suez Canal. It is prevalent and severe in the Kharga oasis and lurks in the Delta to an extent which is only now becoming appreciated. Filariasis, another mosquito-carried disease, possesses foci in the land. An unknown fever resembling both typhus and typhoid but of a relapsing type made its appearance in Cairo in 1914 and accounted for many deaths, undulant fever (a preventable malady) occurs, sand-fly fever claims its victims here and there, diphtheria is not uncommon, rabies is present to a disquieting extent, while skin infections, and more especially boils, show that the plagues of Egypt, if they once ended with the death of the first-born, have assuredly assumed a new lease of life.

## CARCINOMA OF THE RECTUM:

### THE CHOICE OF OPERATION.

By IVOR BACK, M.A., M.B. CANTAB., F.R.C.S. ENG.,  
SURGEON TO ST. GEORGE'S HOSPITAL AND TO THE GROSVENOR  
HOSPITAL FOR WOMEN.

It is my purpose in this article to discuss the relative merits of, and the indications for, the various operations which have been devised for carcinoma of the rectum.

It must be regarded as a lamentable fact that only a small percentage of cases of rectal carcinoma are capable of radical extirpation when first seen by the surgeon. I have asked a number of surgeons to give me their estimate of the percentage of operable cases; the lowest figure was 20 per cent. and the highest 40 per cent. My own experience is that it is about half-way between these figures, rather under 30 per cent. The figures vary in the two sexes. Taking a rough estimate, out of every 100 cases in the female 40 are operable, out of every 100 in the male only 20, giving a figure of 30 per cent. for the two sexes.

#### *Early Stages of the Disease.*

Carcinoma of the rectum probably starts either as a small ulcer or as a small polypoid growth. But how rarely does one come across a case in such an early stage. One would think that either of these would cause sufficient discomfort to arrest the patient's attention and cause him to seek advice. But experience shows that this is not the case, and the majority of patients, even intelligent and educated ones, present at the first examination a large ulcerating process extending more or less completely round the bowel.

The really early cases are so rare that it is easy to remember them.

A lady, aged 37, consulted me in 1912 on account of a single attack of hæmorrhage from the rectum—bright red, not profuse. She had no other signs or symptoms. She did not look ill, and rectal examination was negative. The sigmoidoscope revealed a stalked polypus about the size of a Barcelona nut in the sigmoid colon. I opened the abdomen and excised the polypus with its base and a wide area of the bowel wall surrounding it, and closed the opening with Lambert sutures. She made an uneventful recovery.

Microscopical examination revealed, to my surprise, a typical columnar-celled carcinoma. She has exhibited no signs of recurrence. The case demonstrates the value of sigmoidoscopic examination, if such demonstration is still needed.

But this type of case is the exception. The one we have to deal with most often is that in which a large mass is palpable within reach of the examining finger. The question to be decided is, Is it capable of radical extirpation? I hold very strongly the view that the question cannot be adequately decided unless and until the patient is examined under an anæsthetic. It is sufficient at the first examination to know that there is a carcinoma. Digital manipulation of the growth nearly always causes great pain.

Examination under an anæsthetic will reveal a number of helpful points: (1) the extent of the growth in both directions—i.e., whether it completely encircles the bowel and (if the examining finger can be introduced through the lumen of the growth) how far it extends upwards; (2) the nature of the growth—i.e., whether it is a soft friable fungating mass (as it most often is) or whether it is a hard fibrous ring; (3) the mobility of the growth—i.e., whether it is fixed behind to the sacrum or it front to the bladder in the male or to the posterior vaginal wall in the female; (4) deep palpation of the relaxed abdominal wall may enable the surgeon to feel enlargement of the lumbar glands or of the liver.

#### *Colostomy.*

If such examination reveals the case to be a hopelessly inoperable one a colostomy should be done, and done at once. I remember being taught as a student that the patient should be put on a suitable diet calculated to leave as small a faecal residue as possible and kept under observation; and that a colostomy should only be performed as soon as symptoms of obstruction supervened. This teaching, I believe, to be wholly and utterly wrong, for the following reasons: (1) the patient will get progressively weaker as time goes on and less able to withstand the shock of an abdominal operation; (2) if the surgeon is to wait until symptoms of obstruction supervene there will necessarily be some hypertrophy and dilatation of the descending colon and the operation may be rendered technically difficult; (3) it is probable that deflection of the intestinal contents from passing over the surface of the growth may retard its progress; and (4) last, but not least, the patient is already suffering from some degree of chronic intestinal stasis, and an immediate colostomy will relieve him from the multitude of disorders associated with that condition. In fact, the improvement which often follows colostomy is quite remarkable.

The colostomy should be a hypogastric one, the incision being a vertical one through the centre of the left rectus abdominis muscle just below the umbilicus and a loop of the descending colon brought out and fixed in position by passing a stout glass rod through its mesentery. Hypogastric colostomy has several advantages over inguinal colostomy done through a muscle-splitting incision in the left iliac fossa. The opening is in the centre of the abdomen in a position where the patient can attend to it with the greatest ease and comfort, and the cup remains in position whatever attitude the patient may adopt, whereas in the inguinal colostomy the cup is apt to ride up on the anterior superior iliac spine when the patient sits down and allow an escape of faecal matter. Further, the rectus abdominis develops in the course of time a certain degree of sphincteric power, which the muscles in the left iliac fossa rarely, if ever, do.

Some surgeons perform a transverse colostomy. I do not advise it because the great omentum may make the operation difficult, and my experience is that the spur is rarely as good and there is a tendency to spontaneous closure.

There is a popular idea that to have a colostomy is the worst fate in the world, rendering the owner intolerable to himself and to others, and that it is better to die of the cancer. This is a fallacy which should be combated. Life with a colostomy is not, of course, ideal, but it is far from intolerable; and I know of one medical man who has had a colostomy done for diverticulitis, and now that the diverticulitis is cured refuses to have the colostomy closed and conducts a large practice in comfort.

#### *When is a Radical Operation Justifiable?*

The contraindications may be considered under two headings.

(1) *General*.—Advanced age is a contraindication. It is difficult to lay down an absolute rule; to say, for instance, that radical operation must not be undertaken in an individual of 60 years or over. Some people of 60 are, pathologically speaking, only 50; others are 70. Experience alone can help one to decide on this point. Recognisable metastasis—e.g., enlargement of the liver with umbilicated nodules, or enlarged lumbar glands palpable through the abdominal wall under an anæsthetic—is an absolute contraindication, as is the condition known as cachexia.

(2) *Local*.—Direct extension may have extended so far as to form a recto-vesical fistula. This is an absolute bar to radical operation. Fixation of the growth in any direction, anteriorly to the prostate or bladder in the male or to the posterior wall of the vagina in the female, laterally along either levator ani muscle or posteriorly to the coccyx or sacrum diminishes the prospect of success in proportion to the density of the fixation. Personally I regard dense fixation anteriorly in the male as a definite contraindication. In the female the posterior wall of the vagina can be removed with the bowel. Fixation in other directions is less serious and operability depends upon the degree of it present. In some cases fixation has spread in the direction of all points of the compass and these are inoperable.

#### *Unsound Operations.*

When a decision has been arrived at that the case is operable, what operation should be done? I am convinced that any operation which aims at leaving a normal anus—i.e., any operation which is not associated with a colostomy—is a bad operation. It is pathologically unsound because it leaves behind those very areas which are liable to become the seat of recurrence. Three such operations have been described.

1. Rectorrhaphy or trans-sacral excision of the growth with end-to-end anastomosis. This consists in a few words of removing the coccyx and part of the sacrum if necessary, freeing the portion of bowel where the growth is situated, dividing the bowel above and below the growth and performing an anastomosis of the two ends. It is difficult, almost impossible, to be certain of so removing all the affected tissues as to make reasonably sure against recurrence; the anastomosis rarely, if ever, holds per primam and usually leaves a posterior fistula, which takes weeks or months to heal; and, finally, there is often left an ugly and intractable stricture at the level of the line of suture.

2. The abdomino-anal operation. The early stages of this resemble those of the abdomino-perineal. The abdomen is opened in the middle line, the lower part of the sigmoid and the rectum freed from their attachments and pushed down below the peritoneal pelvic floor, which is reconstituted by suture. The abdomen is closed. The patient is turned on his side. A posterior incision is made and the coccyx removed, if necessary. The rectum is cut away from the external sphincter, which is left but divided posteriorly. The bowel is pulled down as far as it will come and is fixed inside the sphincter, which is reunited. All the bowel distal to the sphincter, this being the portion bearing the carcinoma, is removed at a level of an inch below the anus. This operation is more radical than the last. But if the contents of the ischio-rectal fossa have been thoroughly removed with the levatores ani and the internal sphincter the sigmoid, which has been brought down to replace the rectum, cannot and does not behave like a normal rectum, and infinite trouble with defæcation is usually experienced, not to mention the fact that some degree of stenosis at the anal orifice is a common sequela.

(3) Kraske's operation and its modifications. In this the coccyx, and, if necessary, the lowest part of the sacrum, is removed, a perianal incision is made and the rectum is dissected up until it is free well above the growth. The bowel is divided above the growth and the open proximal end is fixed on to the upper part of the wound as an artificial anus. The artificial anus so formed develops no sort of control, and is in such a position that the patient is totally unable to look after himself. This operation is, in my opinion, quite unjustifiable, and I hope it is falling into disuse.

#### *Satisfactory Radical Operations.*

There are, as I think, only two satisfactory radical operations for carcinoma of the rectum: (1) the combined abdomino-perineal, and (2) colostomy with high perineal excision later, which I will call for short the two-stage operation, and I propose to discuss their respective merits.

(1) The combined abdomino-perineal operation. I do not propose to describe the technique in detail since it is sufficiently well known. The abdomen is opened by a paramesial incision with the patient in the Trendelenburg position, the inferior mesenteric artery is divided between

ligatures, and an incision made in the mesentery of the colon on either side. These incisions are produced to meet in front of the sigmo-rectum. A separate incision about two inches long is made through the centre of the left rectus abdominis muscle. The bowel is divided at the apex of the omega loop, and both ends are closed with a basting stitch. The proximal end is brought out through the separate opening and fixed in position so as to form a terminal colostomy. It is well to make a small incision in the exposed end and tie in a catheter, as advocated by Mr. Sampson Handley. This has two advantages: (i.) flatus can escape, and (ii.) saline infusions can be given through the catheter if desired. The distal end is freed from its connexions and pushed down into the pelvis, and the peritoneal pelvic floor is restored above it by suture. The abdomen is closed and the patient turned on the left side. The anal orifice is closed with a running suture and an incision made round it, which is continued upwards in the middle line behind. The coccyx is removed if necessary. The connexions of the rectum proper are cut through at as wide a distance from the bowel as possible. The levatores ani should be divided near their origin, and the whole of the bowel below the point of section is removed en masse. A large drainage-tube is inserted in the posterior wound and the skin edges brought together with sutures.

(2) Colostomy with excision at a later stage. In this a hypogastric colostomy is performed and opened on the third or fourth day. A fortnight later, when the colostomy is well established and working adequately, the second stage is undertaken. The anus is closed, an incision made round it and extended upwards in the middle line behind and the coccyx removed as in the abdomino-perineal operation. The connexions of the rectum are cut through as far away from the bowel as possible; and the freeing of the rectum is continued upwards carefully and gradually until the pelvic peritoneal floor is reached anteriorly. The peritoneum is deliberately opened and the freeing of the bowel is continued, clamping the vessels on its posterior aspect until a portion of bowel completely covered by peritoneum can be comfortably reached. A clamp is put on at this level and the distal portion of bowel is removed. The proximal end is closed with a basting stitch, and its closure made further secure by a superimposed circumferential Lembert suture. This end may be allowed to drop back into the peritoneal cavity or may be fixed to the pelvic peritoneum. The pelvic peritoneum is formally closed, as in a laparotomy. A tube is inserted for 48 hours in case of oozing and the skin edges brought together by suture. Primary union of the posterior wound should result.

The important thing is that the bowel should be brought down so far that it is divided at a point where it is completely covered by peritoneum. If this is done it can be returned to the peritoneal cavity without risk. Any attempt to divide the rectum below the pelvic peritoneal floor means that a portion of bowel uncovered by peritoneum is left in the pelvis. The stitches give way and a fistula results which may persistently refuse to close, and first intention healing of the posterior wound (a point of prime importance to the patient's comfort) is impossible.

At first sight the abdomino-perineal operation appeals to the imagination as the more radical and therefore sounder procedure. But it has to be confessed that the abdomino-perineal operation is associated even now with a high primary mortality—i.e., death as the immediate result of the operation. When it was first introduced this mortality must have been at least 40 per cent. It is difficult to get exact figures, but that is my impression. With our improved technique of to-day, and the more judicious selection of suitable cases, the figures have shown an improvement. At this date I estimate the primary mortality as being roughly 15 per cent. in females and nearly 25 per cent. in males—that is, 20 per cent. in all cases, a formidable consideration for any surgeon to face.

#### *Common Causes of Death.*

These are: (1) *Shock*. This can be largely combated by giving a continuous submammary infusion of saline during the course of the operation.

(2) *Peritonitis*. This is a low form which makes its appearance recognisable clinically about the fifth or sixth day, and death ensues two or three days later. It is due to soiling of the peritoneal cavity at the moment when the bowel is divided and its ends sutured; in other words, to indifferent technique. But in spite of every possible precaution, it must be admitted that it does occur.

(3) *Intestinal obstruction.* This is generally due to one or more coils becoming fixed by plastic adhesions to the line of suture restoring the pelvic floor and acutely angulated, or as happened in one of my cases, to a coil becoming strangulated round the colon at the back of the colostomy wound. This occurs a few days after the operation and the patient is rarely in a condition successfully to withstand the shock of another laparotomy even if the diagnosis be made in time.

In 1915 I myself lost four male patients consecutively in whom I had performed the abdomino-perineal operation, one from shock, one from peritonitis, and two from intestinal obstruction.

On the other hand, the primary mortality of the two-stage operation should be nil or, at any rate, so small as to be negligible.

#### *A Question for Consideration.*

This, then, is the question we should put to ourselves. Is the possibility of radical extirpation of the growth with freedom from recurrence so much greater in the combined abdomino-perineal operation than in the two-stage operation that we are justified in facing the extra risk of its primary mortality? The only difference between the patients after the two operations is this—that the patient after the two-stage operation still retains a portion of bowel distal to the apex of the omega loop.

The question, therefore, further resolves itself into this. Is this portion of bowel a common seat of recurrence? It need hardly be remarked that recurrence is due to: (a) indirect extension, and (b) direct extension. Indirect extension spreads either by the portal venous system to the liver or by the lymphatics to the retro-peritoneal glands. It does not concern us in this argument, since in neither operation is any attempt made to deal with it. In fact, as I said above, if its presence is clinically recognisable it is a contraindication to radical operation.

Direct extension may be (i.) intramural or extramural. My own belief is that intramural extension certainly takes place round the bowel and down the bowel, but that if the growth extends *up* the bowel it does so only for a very short distance. I have yet to be convinced that the bodies which have been described in the submucous layer of the bowel at a distance of some inches from the growth are carcinomatous at all, and I have not seen a case where a fatal recurrence has taken place in the bowel left after a free perineal intra-peritoneal excision.

But direct extramural extension is a different matter, and I believe that the most important channel by which the growth extends is the fascia covering the levator ani. When we see a recurrence after a radical operation for carcinoma of the rectum it is usually in the form of a fungating mass which has spread down the wall of the ischio-rectal fossa and fungated through the skin in or near the line of the posterior incision; it has, in fact, spread down from a portion of the origin of the infected levator ani which was left behind.

If this is so, the possibility of eradicating the disease should be equally great in the two-stage operation as in the combined abdomino-perineal. I am therefore putting forward my view that considering the respective mortalities of the two operations the two-stage operation should be regarded as preferable in the great majority of operable cases of carcinoma of the rectum; it should be the operation of election.

There is, however, one class of case where the two-stage operation is not feasible and the abdomino-perineal is the only one which gives a chance of removing the growth—i.e., where the carcinoma is situated at the junction of sigmoid and rectum, too low down to admit of excision and end-to-end anastomosis from above and too high up to allow of excision from below.

#### *Conclusions.*

(1) Only 30 per cent. of cases of carcinoma of the rectum admit of radical operation when first seen.

(2) When radical operation is impossible, a hypogastric colostomy should be done *at once*.

(3) Radical operations which aim at retaining the anal canal are pathologically unsound.

(4) The only sound radical operations are: (i.) the two-stage operation (colostomy and intraperitoneal excision by the perineal route later); and (ii.) the combined abdomino-perineal operation.

(5) Of these, the former is the better except in the case of a growth situated at the junction of the sigmoid and the rectum.

## NOTE ON A METHOD FOR THE SEDIMENTATION OF TUBERCLE BACILLI IN SPUTUM.

By J. G. GREENFIELD, M.B., M.R.C.P., B.Sc.;

AND

J. ANDERSON,

FORMERLY PRIVATE, R.A.M.C.

THE following method has been in use for over a year in the laboratory connected with a large military chest hospital, which was constantly receiving fresh cases of suspected phthisis. Up to 20 samples of sputum per diem have been dealt with by its use, and we have found it so much more practical and reliable than any of the published sedimentation methods that we think it is worth while to make it more generally known.

#### *The Method Described.*

5 c.cm. of sputum are mixed with twice their volume of—

Sod. carb. (cryst.)	...	...	...	...	...	1
Acid carbolie (cryst.)	...	...	...	...	...	1
Water	...	...	...	...	...	100

in a centrifuge tube; the tube is then covered with a rubber cap, shaken for a few minutes and put in the incubator for 12 to 24 hours. (If a number of sputa are to be tested they can be placed in numbered tubes in an ordinary test-tube rack and kept in order during further stages.) At the end of the time the tubes are centrifuged for about 15 minutes, the supernatant fluid poured off, and films made from 2 to 4 loopsful of the deposit are stained in the usual way.

#### *Advantages.*

The chief advantages of this method are as follows:—

1. Its rapidity, as it really takes less time than the direct smear method, especially if a large number of sputa have to be examined, as the rapidity with which the frankly positive sputa can be picked out more than compensates for the slightly longer technique.

2. The sputa when taken out of the incubator are sterile in the majority of cases. We have cultured many sputa on to Dorset's egg medium with uniformly negative results both as regards tubercle bacilli and pyogenic organisms. Of two guinea-pigs inoculated from sputa containing numerous tubercle in every field, only one became infected. This pig was injected with 2 c.cm. of a very purulent deposit which contained vast numbers of tubercle bacilli. It would doubtless be possible so to arrange the strength of carbolie used that the pyogenic organisms would be killed off, leaving some viable tubercle bacilli; but for routine laboratory work the advantages of killing off the bacilli before making the smears cannot be over-estimated.

3. The films resemble the direct smears both in the relative proportion of other organisms present and in the presence of mononuclear and polymorphonuclear cells, but the mucus is not stained.

Table showing Number of Bacilli Counted in 15 Fields.

No. of case.	Direct smear.	Ellermann's method.	Simplified method.	No. of case.	Direct smear.	Ellermann's method.	Simplified method.
1	49	47	251	11	15	18	98
2	19	109	107	12	76	+	+
3	1	+	+	13	38	96	161
4	5	149	120	14	0*	6*	14*
5	2	7	17	15	2*	104	150
6	5	72	111	16	20*	+	+
7	16	26	204	17	12*	104	126
8	14	453	537	18	397	+	+
9	0	5	68	19	2	16	99
10	0	5	7	20	25*	67*	200*

+ = more than 1000.

\* = after prolonged search.

The relative ease with which tubercle bacilli can be found by this method, as compared with the examination of the direct smear and of films made by the full technique of Ellermann and Erlandsen, is shown in the above table. In almost every case as many, or more, bacilli were found by the simplified technique, and the advantages both as regards cleanliness and time are obvious.

# A CASE OF LYMPHADENOMA WITH PERIODIC PYREXIA

("PEL-EBSTEIN DISEASE").

BY ADOLPHE ABRAHAMS, M.D. CANCER,

M.R.C.P. LOND.

OFFICER I/C, MEDICAL DIVISION, CONNAUGHT HOSPITAL, ALDERSHOT;  
DISTRICT CONSULTING PHYSICIAN TO THE ALDERSHOT COMMAND.

I AM encouraged to publish this case, not because I am in a position to contribute any new ideas, but because I think its publication will serve some purpose in drawing attention to a condition which, though well recognised, is comparatively rarely encountered and which offers some points of interest in diagnosis. I venture to think, also, that this case is an exceptionally striking example and in many respects more typical than those which have been previously described.

## Cases Reported by Other Observers.

Sir Frederick Taylor contributed a very complete and exceedingly interesting account of "the chronic relapsing pyrexia of Hodgkin's disease."<sup>1</sup> His article included a reference to the previous literature on the subject, a reference which I have found of the greatest value in enabling me to trace the original descriptions by Pel, Ebstein, and others. His detailed description of these cases, together with a résumé of the types of pyrexia which are encountered, I shall briefly epitomise before referring to the case I have myself had the opportunity to observe.

Sir Frederick Taylor points out that the following types of fever may be encountered in cases of lymphadenoma: (1) A continuous pyrexia with slight diurnal variations. (2) Alternating periods of pyrexia and normal temperature. (3) Daily variations of temperature (in excess of the normal physiological limits) which are higher in the evening than in the morning. (4) Mixed types. Cases exhibiting at different times temperature phenomena corresponding to more than one of the above-mentioned types.

Ebstein published a paper entitled, "Chronic Relapsing Fever, a New Infectious Disease."<sup>2</sup> He first gave a detailed description of the clinical peculiarities of the case and afterwards its termination with the condition found at autopsy. His case was under observation for 238 days, during which there occurred 10 attacks of pyrexia, each of 13-14 days' duration, with apyrexial intervals of 10-11 days. An eleventh attack was of longer duration and

that this pyrexial variety of lymphadenoma is more frequent under than over 20.) There was no history of any antecedent illness, and he was admitted on Oct. 3rd, 1918, with "influenza." At that time the hospital was inundated with cases of pyrexia, all of which, very naturally at that time of epidemic, were, in the absence of any distinctive features, labelled, provisionally at any rate, influenza; and although it is probable that on his admission the disease from which he was suffering was a mild attack of influenza, no particular attention was attracted or directed to anything which might have suggested the subsequent diagnosis. He was sent to a convalescent hospital on Oct. 15th, and 28 days later he was returned with a history of attacks of pyrexia and malaise, of greatly enlarged spleen, and of doubtful signs of fluid in the left side of the chest. On his arrival he complained of no symptoms, his temperature was subnormal, no physical signs were present, but the spleen was very definitely enlarged and extended three fingers' breadth below the costal margin.

Three days later the spleen was quite impalpable, and in the absence of any other explanation it was thought that the patient was now convalescent from what was a fever of the typhoid group. But on the 22nd there was a recrudescence of pyrexia and malaise, with gradual but rapid enlargement of the spleen. Pathological investigations instituted at this time gave the following results:—

Total leucocyte count, 1560 per c.mm. Differential count: polymorphonuclears (per cent.) 47, lymphocytes 39, large monocytes 12, eosinophiles 1, mast cells 1. Erythrocytes, 2,675,000 per c.mm. Haemoglobin, 52 per cent. Blood film showed anachromasia of red cells; otherwise nil abnormal. Urine nil. Blood culture negative. It will be observed that resemblance to typhoid fever is again manifest in the leucopenia.

Apart from the enlarged spleen no abnormalities were ascertainable; there was no trace of enlarged lymphatic glands. It will be remembered that these negative findings were characteristic in the cases described by Ebstein and Pel.

## Remarks.

Many chronic infections are capable of producing an irregular sort of fever. "Anomalous typhoid," "anomalous influenza," tuberculosis, Malta fever, were all specifically excluded. It may be added that the picture of true relapsing fever differs from that of the condition described, in that the periods of pyrexia terminate suddenly by an unmistakable crisis, quite apart, of course, from the unequivocal evidence afforded by the spirilla in the blood. Cases of lymphadenoma without any enlarged external glands are sufficiently rare to

was followed shortly before death by a brief twelfth attack. During life an enlarged spleen was identified, but no abnormal appearances in the blood and no enlargement of external lymphatic glands were observed. At the autopsy there were discovered enlarged bronchial, mediastinal, and mesenteric glands, as well as nodules of lymphoid appearance in the lungs, liver, kidneys, and spleen. Both liver and spleen were substantially enlarged and both exhibited infarcts.

Pel's case was described actually two years before Ebstein's publication. He referred to his case under the title "Pseudoleukæmia or Chronic Relapsing Fever?" At that time the association of pyrexia with Hodgkin's disease was unknown. Again, in Pel's patient, as in Ebstein's no enlarged external glands were evident, although hyperplasia of the spleen, retroperitoneal, mesenteric, and bronchial glands was found post mortem. Pel's idea was that the exacerbations of fever were produced by solid food, a view which nobody else has supported, and one, indeed, which observation appears completely to refute.

## The Author's Case.

The patient whom I have had the opportunity to investigate was a boy 17 years of age. (It appears from Taylor's account

excuse the failure to diagnose the patient's illness earlier, but once the condition has been recognised it may be said that the occurrence of such periods of pyrexia with corresponding periods of enlargement of the spleen afford a most characteristic picture.

Osler, in referring to this disease, says:—

"In a few rare instances (of lymphadenoma) Pel has described remarkable periods of fever of 10 to 14 days' duration, alternating with intervals of complete apyrexia. They occurred in two of my cases. Ebstein described it as a form of chronic recurring fever. It is probably due to an intercurrent infection."

The last suggestion would appear to be indisputable, and, bearing in mind the character of the pyrexia, one would suspect the parasite to be of a protozoal character. So far as I am aware, no supposed infective agent has been identified. During one pyrexial period of the present case the spleen was punctured and the blood extracted examined bacteriologically, but with negative result.

Little further description of the case is necessary. As will be seen from the chart, a remarkable regularity of periods of pyrexia and apyrexia was on the whole sustained, although the apyrexial intervals were on two occasions only one-half the usual duration. During each period of fever the spleen increased in size, although not to so great an extent in the last periods observed as in the earlier intervals.

<sup>1</sup> Guy's Hospital Reports 1906 vol. ix.

<sup>2</sup> Berl. Klin. Woch., 1887, vol. xxiv., pp. 365 and 337.

During the apyrexial phases the patient always felt quite well and walked about, taking ordinary diet, and regaining the four or five pounds' weight he had lost during the previous period of pyrexia. So far as I could estimate, his general condition on Feb. 15th was no worse than on his first admission to hospital. He was transferred in order to be nearer his home, and it is probable therefore that at some future date a further history of the progress of the case will be forthcoming.

I must express my gratitude to Lieutenant-Colonel W. Turner, C.M.G., R.A.M.C., O/C. Connaught Hospital, Aldershot, for permission to publish the notes of this case, and to Lieutenant-Colonel Herbert French, R.A.M.C., consulting physician to the Aldershot Command, to whom I am indebted for much valuable advice in the investigation thereof.

## THE RELATION OF GRAVES'S DISEASE TO DIABETES AND GLYCOSURIA.

By R. T. WILLIAMSON, M.D., F.R.C.P.,

CONSULTING PHYSICIAN TO THE ROYAL INFIRMARY, MANCHESTER.

A NUMBER of interesting facts indicate the relation of Graves's disease to diabetes mellitus and glycosuria. Many writers have drawn attention to this relationship. In this paper, however, I do not propose to refer to interesting articles already published on the subject, but shall briefly refer to cases in my own practice which illustrate this relation from the clinical side.

1. Graves's disease is occasionally followed by, or associated with, diabetes mellitus, well marked or mild.

(a) Graves's disease followed by *severe* diabetes mellitus.

CASE 1.—Mrs. A. H., aged 47. Seven years before she came under my observation she had suffered from a very severe mental shock. Her husband's hand was torn off in an accident at his workshop. The patient was greatly shocked on hearing of the accident, and the mental distress was very soon followed by symptoms of Graves's disease. For some time these were severe; then she improved slowly; but about six years after the shock thirst and symptoms of diabetes were noted, the symptoms of Graves's disease having persisted.

When admitted into hospital under my care definite symptoms of Graves's disease could still be detected, though they were not very marked (exophthalmos, tachycardia, pulse 120 to 180, thyroid slightly enlarged, and fine tremor of hands). Symptoms of diabetes mellitus of medium severity were also detected. She was under my care in hospital for three months and was treated for diabetes, which was the prominent affection. The sugar in the urine was estimated daily. The daily amount of urine during this period varied from 80 to 140 ounces, but sometimes it was more than the latter figure; sp. gr. 1030 to 1040; sugar 18 to 30 gr. to the ounce (about 4 to 6.5 per cent.), total amount of sugar in 24 hours 1500 to 2000 gr. In course of time the urine gave a deep reaction with ferric chloride for diacetic acid; then albumin was detected in the urine, and finally casts. Death occurred from a sudden attack of hemiplegia.

CASE 2.—Mrs. J., aged 39. Suffered from Graves's disease at the age of 21; goitre, palpitation, and other symptoms well marked. Suffered for four years from these severe symptoms (seen by the writer at that time). Then recovered practically from Graves's disease, but suffered long from attacks of asthma. At the age of 35 diabetes detected. At the age of 39 seen by writer again. Marked diabetes; diacetic acid also found in urine in large quantity. No goitre, pulse 108; only slight prominence of eyeballs; no tremor.

CASE 3.—Mrs. M., age 41. Symptoms of Graves's disease developed at the age of 17, and continued until the age of 30. Then practical recovery occurred. At the age of 40 symptoms of diabetes developed and eyeballs became again prominent. When seen by writer at the age of 41 the symptoms and urinary condition were those of severe diabetes; also the eyeballs were prominent and the pulse rapid, 104, but the thyroid was not enlarged.

(b) Graves's disease followed by *mild* diabetes mellitus (or persistent glycosuria).

CASE 4.—Male, aged 39. At age of 34 Graves's disease developed after a period of excessive mental work. Palpitation, exophthalmos, tremor, and thyroid enlargement developed. A trace of sugar was detected in the urine for a time. After careful treatment the symptoms of Graves's disease gradually diminished, and the urine became quite free from sugar. Two years later, at the age of 36, he began to suffer again from severe palpitation and was obliged to discontinue all work. Three years later, at the age of 39, a trace of sugar was again detected in the urine; but a month later the urine was free from sugar. A month afterwards sugar was again detected, and the glycosuria continued. The condition developed into one of mild diabetes mellitus or persistent chronic glycosuria, the urine always containing sugar. (Urine 60 oz. daily, later 90 oz., sp. gr. 1018, considerable amount of sugar, no albumin, no diacetic acid.) The patient lost weight very much. He became nervous and excitable; pulse 120; no thyroid enlargement; eyes not prominent, but Stellwag's and von Graefe's signs, and slight tremor of hands detected. After 8 months the urine became quite free from sugar; and he gained flesh. No exophthalmos could be detected, the thyroid was practically normal, pulse 96, no tremor. With exception of insomnia he was practically well.

CASE 5.—Middle aged man, goitre well marked. Marked palpitation, and exophthalmos; persistent glycosuria. No other diabetic symptoms.

CASE 6.—Young man; typical symptoms of Graves's disease; persistent glycosuria; no other diabetic symptoms.

2. In Graves's disease frequently a temporary or intermittent slight glycosuria can be detected. This fact is well known, and examples need not be given.

3. Mild diabetes is, in rare instances, followed by Graves's disease; such cases are extremely rare. C. Grube has recorded the case of a patient who was greatly shocked by hearing that her urine contained sugar. The amount was only small, but the mental shock was great owing to the fact that a relative had died of diabetes. In a very short time Graves's disease developed and steadily advanced and proved fatal.

4. *Graves's disease and alimentary glycosuria.*—In Graves's disease alimentary glycosuria is often produced much more readily than in health by the administration of a large quantity of sugar. In some cases of Graves's disease glycosuria is produced by 20 or 30 g. of grape sugar, whilst in others 100 g. are required to produce this effect. (In healthy persons 180 to 250 g. of grape sugar are required to produce alimentary glycosuria—v. Noorden.)

5. Both Graves's disease and diabetes mellitus occasionally develop directly after a sudden mental shock, or after great mental anxiety of short or long duration.

Thus in Case 1 recorded in this article symptoms of Graves's disease developed in a female after the mental shock of hearing her husband's hand had been torn off in an accident at his work. In another of my cases the symptoms of Graves's disease developed in a young female directly after the great mental shock caused by seeing a boy knocked down in the street by a motor-car. In a third case they followed the mental shock caused by the capsizing of a small boat in which the patient was rowing on a river. In another instance I was called to see a man who was dying of acute pneumonia. At that time his daughter was apparently not suffering from any illness. The man died next day. The shock to the daughter was very great and she began to suffer from severe palpitation. The symptoms increased rapidly and a month after the father's death I was called to see the daughter, and found her to be then suffering from marked Graves's disease.

Probably in these cases the mental shock was the last factor, or exciting cause, in the development of the disease in individuals whose nervous system was already in some way abnormal.

In diabetes mellitus we also sometimes find that the disease has developed directly after a sudden mental shock. I have recorded a number of striking instances.<sup>1</sup>

Amongst discharged soldiers we now find many cases of Graves's disease, and my own impression is that the number of cases of Graves's disease amongst discharged soldiers is much greater than the number of cases amongst men in civil life before the war.

As regards diabetes mellitus, however, I am inclined to think that this disease is certainly not more common in discharged soldiers than amongst the male civil population of military age before the war. These are, however, only general impressions and not based on statistics.

6. *Family history of diabetes in cases of Graves's disease.*—Occasionally the history shows that the two diseases have occurred in different members of the same family. If we take the family history in cases of diabetes we occasionally find that one or more relatives have suffered from Graves's disease, and if we take the family history in cases of Graves's disease we occasionally find that one or more relatives have suffered from diabetes mellitus. The following are a few examples:—

1. Mrs. S. consulted me on account of diabetes mellitus. One daughter had died of diabetes mellitus four years previously. Another daughter developed Graves's disease afterwards. The daughter of the brother of Mrs. S. suffers from Graves's disease. The brother of the husband of Mrs. S. suffers from diabetes mellitus.

2. Male; severe diabetes mellitus. Sister suffers from Graves's disease.

3. Female; Graves's disease. Mother suffered from diabetes.

4. Female; Graves's disease. Father, one brother, and a cousin all suffering from diabetes mellitus.

5. Female; Graves's disease. Mother and one brother suffer from diabetes mellitus.

6. Girl, aged 6; diabetes mellitus. Father's brother and father's cousin suffered from diabetes mellitus. Another cousin of father suffered from Graves's disease.

7. Female; Graves's disease. Father and mother, mother's sister, and mother's father all suffered from diabetes.

Many other points of interest respecting the relation of the two diseases, based on experimental work, might be added; but in this note I desire to refer only to the clinical

<sup>1</sup> Brit. Med. Jour., Feb. 2nd, 1918, and book on "Diabetes Mellitus and its Treatment." Lond. and Edin. 1898.

facts. As von Noorden states with reference to the action of the thyroid gland and the pancreas:—

"Here we are in no doubt whatever. The thyroid and pancreas have antagonistic actions, the former inhibits the excitability of the latter. The more powerful the action of the thyroid the more marked the inhibition."<sup>2</sup>

The recovery from Graves's disease or the marked improvement in the symptoms, followed by the development of diabetes, and the other facts mentioned in this article, also raise the question as to the possibility of both of these diseases, in certain cases, being due to fine changes in the nervous system (? medulla)—changes which, by vaso-motor or other influence, at one time produce Graves's disease by altering the thyroid activity, and at another time, by extension to adjacent parts of the central nervous system, alter the activity of the pancreas.

7. *Graves's disease and acetonæmia.*—In Graves's disease occasionally the patient suffers from nausea, sickness, and persistent vomiting, and may be unable to take food and may rapidly become very wasted. In some of these cases we find a marked diacetic acid reaction in the urine (claret coloration with perchloride of iron), though the urine is free from sugar. The condition resembles the acetonæmia of diabetic coma in many respects. (A similar acetonæmia, apart from diabetes, is occasionally observed in cases of persistent vomiting from gastric affections and in a number of other affections.)

#### Remarks on Treatment.

The occasional development of diabetes after Graves's disease, and the frequent occurrence of temporary or intermittent glycosuria in this disease, are facts which should be considered in the treatment. I think it is advisable in the treatment of all cases of Graves's disease to discontinue the addition of sugar to food and drinks, and also to avoid foods and drinks which contain much sugar. These precautions are especially desirable and sugar and sweet food should be cut off entirely if glycosuria, temporary or intermittent, has ever been detected. Not infrequently in the treatment of Graves's disease nitrogenous foods are restricted or cut off, and a diet chiefly of non-nitrogenous food is given; but if such a diet is advised I think it desirable that the *sugar* carbohydrates should be much restricted, as just stated.

If glycosuria is frequent or permanent then a diet chiefly of *starchy* carbohydrate food is unsuitable in such cases of Graves's disease. In definite diabetes, associated with or following Graves's disease, of course the diet suitable for the form of diabetes detected should be advised, as the diabetes is usually more serious than the Graves's disease.

To these statements one exception may be mentioned. In cases of Graves's disease complicated with persistent vomiting, with acetonæmia, and with diacetic acid in the urine, if no glycosuria is detected *sugar* carbohydrates, such as sweet fruit, tinned apricots, and syrup of such tinned fruits, may be of much service for a *short time*, along with alkalis (citrate of soda or potash, or bicarbonate of soda in large doses). I have found such treatment followed by sudden marked improvement in the condition just named when vomiting has been most persistent, obstinate, and serious.

Many cases of Graves's disease, especially incompletely developed forms, are now met with amongst demobilised soldiers, and the points just mentioned, as regards diet, are worth bearing in mind with respect to the prevention of diabetes or glycosuria as a complication, or at a later date.

<sup>2</sup> New Aspects of Diabetes. By Professor von Noorden. Bristol, 1912, p. 59.

MEANS TO AVERT MENTAL COLLAPSE.—Dr. M. J. Nolan, in the forty-ninth annual report of the Down District Lunatic Asylum (of which he is resident medical superintendent), pays a tribute—probably the first of its kind or, indeed, of any kind—to the out-of-work or unemployment donation. While admitting it was not without evil results in other directions, he thinks it undoubtedly operated to save many deserving individuals from complete mental collapse arising from anxiety about the future, following a long period of stress. The rate of admission to the Down District Lunatic Asylum has fallen, the total population of which in 1918 was 714, with an admission of 105 (53 men and 52 women).

## CHOLERA OF THE SHEEP

(JAUNDICE; YELLOWS OR YELLOWSES; HEADGRIT OR PLOCACH).

By J. P. MCGOWAN, M.A., M.D., B.Sc., M.R.C.P. EDIN.

(From the Johnston Laboratories, Bacteriological Department, University, Liverpool.)

THE epizootic and enzootic disease of sheep dealt with in this preliminary article is recognised throughout Scotland, under the various synonyms given above, during the months of August and September usually. It affects lambs of the year usually, that is to say, when they are about six months old. The names "jaundice," "yellows," and "yellowses" are derived from jaundice being present in some cases, whilst "headgrit" refers to a swollen condition of the head in the parotid region, also occurring in certain cases. The term "plocach" is Gaelic and is synonymous with headgrit, meaning, as it does, "big head" or swollen head. The designation of the disease by the name of cholera is a proposal of my own, justifiable, in my opinion, as will be seen later, by the frequency of choleraic symptoms. That the disease has not before this been designated by farmers and shepherds with a name indicative of these important symptoms may in part be explained later.

#### Account of the Disease by a Farmer.

I had my attention first drawn to this condition in September, 1915, by the receipt of a letter from a farmer in whose flock the disease was markedly present. This letter may form a fitting introduction to a discussion of the natural history of the condition and is quoted in full. Under the date of Sept. 9th, 1915, he writes as follows:—

"From August 12th up to the present date I have lost 61 lambs with the disease. In only one or two cases was the death sudden. Most of the lambs after being noticed ill, linger for some days, and in some cases longer, on to a fortnight. I have one or two which have lived on for three weeks.

Most of them start with a scour and in a day or two shrink to nothing. They just hang about, and if water is available drink constantly. If they are unable to get to water they hang about the hedges with nose down and very dull, lie down for a few minutes and then up again. Some of them emit a grunt when breathing. Others of them froth at the mouth, but the froth is not blood-stained. They also dribble saliva from the mouth when they can get water.

Most of them that I have seen skinned and opened have a lot of water in the stomach and intestines, while their skin is glued to their flesh and very difficult to take off. When one of the ailing sheep is caught hold of, you can hear the water jumbling about inside.

On opening them we have found, as a rule, the fourth stomach and the gut proceeding from it much congested and discoloured, and in most of them a gritty stuff like the husks of cotton cake and sand mixed (no great quantity, however). The other stomachs are mostly quite natural. In one or two cases we found the first and second stomachs compacted with dry, hard faeces. There seems to be no food in the bowels, only a greenish-yellow water.

Their livers are, as a rule, all right, but in one or two cases they are much inflamed and brittle. The kidneys seem all right and are quite firm. Diaphragm is often inflamed and dry. There is no water or fluid in the chest. The heart is natural and the pericardium contains no excess of fluid. Lungs in most cases (all I have seen) are much inflamed and discoloured (one, however, finds this often in cases of illness which hang on for some time).

We have had a good few yellowsed sheep (with jaundice, swollen head, and loss of ears) this season, and they are by no means immune. Also many of those dying are affected with 'orf' (lip and leg evil).

The cases look to me more like poisoning of some sort. The whole of the sheep have had a biggish check, not only those which have died or are ill, and I cannot conceive how they have got the check, as the treatment has been good all along.

The grass this year is very rank, but when most of the cases occurred it was a clean hay faggage. We have some cases from a field which was 'hained' for a bit, and this field is very rank and a bit 'tathy,' but nothing to complain of. The lambs on this grass are getting tares laid down to them. Those on the fog are being run off at nights on to an old grass field and are now getting turnips."

At the request of the owner I visited the flock on Sept. 17th and was able to confirm the substantial

accuracy of his observations as just given. I ascertained further from the shepherd that the affected animals "squirited out" the fluid bowel contents. There were two lots of lambs on the farm. The worst affected lot was on a field with very rank foggage; the lot that had practically no cases was on a better pasture, inasmuch as it consisted more largely of clover. Several of the surrounding farms were affected with the disease.

#### Summary Account of the Disease.

The facts thus ascertained with regard to the disease may be shortly summarised as follows. It is an epizootic disease affecting lambs during the months of August and September. Affected animals in the fatal cases live for a period varying from a few days up to a fortnight or three weeks. The disease commences with a colliquative diarrhoea, and in a few days the animals shrink markedly in size. The disease is characterised by great thirst. Jaundice and headgrip cases and cases with loss of ears are occurring at the same time, and these cases are affected with this same diarrhoea. There is marked dryness of all the tissues of the body on post-mortem examination; the intestinal tract, however, is empty of food and is full of a large quantity of a greenish-yellow watery fluid, which can be detected during the life of the animal by its "jumbling." There is marked inflammation of the fourth stomach and duodenum. The fact of the whole of the lambs, apart from those obviously ailing, having received a bad check would seem to indicate that there were a large number of them suffering from the disease in a milder and not so noticeable form. It is a disease with a high mortality at times and can cause great financial loss to the owner.

#### Post-mortem Findings.

On the occasion of my visit time and circumstances did not permit of me doing an exhaustive series of post mortems and on account of various factors I had not an opportunity of revisiting the farm during the continuance of the disease. I performed, however, two post mortems, one on an acute case and the other on a chronic case, and the record of these cases are as follows:—

*Lamb 1.*—This lamb was seen ill for the first time on the preceding night. On examination copious colliquative diarrhoea was present; very dull and listless; temperature in rectum 105° F. Killed by bleeding from throat. It was in fairly good condition. There was no gangrene of ears, no swelling of parotid region, no jaundice. No discharge from nose, no frothing at mouth; no hæmorrhages subcutaneously or in muscles. The lungs were healthy; no effusion into pericardium. Heart healthy, including valves; no myocardial hæmorrhages. The liver was apparently healthy; no flukes; gall-bladder very large and very full of green bile. The kidneys, spleen, pancreas, and bladder were apparently healthy. The first stomach contained a quantity of moist grass; the fourth stomach was inflamed and contained a little clear watery fluid, but no food; duodenum was markedly inflamed. In jejunum, ileum, cæcum, colon, &c., no evidence of inflammation. The whole intestinal tract from the duodenum to the rectum was filled with a greenish fluid devoid of solid matter. No round worms or tapeworms were found. The mesenteric glands were not enlarged or congested. When this animal was lifted up prior to being killed the jumbling of the intestinal contents was distinctly heard and felt.

*Lamb 2.*—This case, a chronic one, dated from the onset of the disease in the flock about August 19th. It appeared to be getting better slowly, but latterly became very emaciated and dwindled to a shadow. When seen the emaciated condition was noted, as also that the animal was suffering from diarrhoea. There was no evidence of difficulty of breathing; its temperature was not taken. It was killed by bleeding from the neck. There was no gangrene of ears, no swelling of parotid region, and no jaundice. No discharge from nose and no frothing at mouth; no hæmorrhages subcutaneously or in muscles. The lungs and heart were perfectly healthy except for a few worm nodules in lung. There was no enlargement or congestion of the lymphatic glands anywhere. The liver was much enlarged and very fatty. Gall-bladder was much distended, and contained a golden-yellow watery fluid; turbid with particulate material. The wall of the gall-bladder was thickened, and its lining membrane inflamed. No flukes in the liver or bile passages. The spleen, kidneys, pancreas, and urinary bladder appeared healthy. The first, second, and third stomachs contained moist grass; fourth stomach congested and contained a watery fluid. The duodenum showed an intense hæmorrhagic inflammation with a diphtheritic exudate on its surface. No apparent congestion of the ileum, cæcum,

colon, rectum. The contents of the intestine were greenish and watery, containing slightly more solids than was the case in Lamb 1. There were a few whip-worms in the cæcum; no other round worms or tapeworms found.

The points to be specially noted are with regard to the acute case, the watery contents of the intestine, and the inflamed nature of the duodenum. In the more chronic case attention may be drawn to the character of the intestinal contents, to the condition of the duodenum, liver, and gall-bladder, and to the emaciated condition of the animal.

#### Bacteriology.

Facilities for an extensive bacteriological examination, under the circumstances, were not good and I confined myself to doing a little, and, if possible, doing it well. With the idea that the acute case would be the most likely to contain the cause of the disease, I ligatured a portion of the duodenum and removed it to the laboratory in a sterile bottle. Suspecting that the conditions found in the more chronic case might be caused by secondary invaders I contented myself with making a careful naked-eye examination of the specimens. As the sequel will show, portions from the liver for histological and the contents of the gall-bladder for bacteriological examination might have been of great service in helping to elucidate the condition further.

Before proceeding to record the experimental results obtained with the material removed from Lamb 1, it might be well here to deal with any literature bearing on the subject. There are many references scattered through the books dealing with such conditions as jaundice, but the only notice which I can find bearing indubitably on the disease entity described above occurs in May's book on the sheep.<sup>1</sup> Under the names acute jaundice, hepatitis, the bile condition, bile fever, he describes a disease which, he states, had occurred very seldom in Germany, but had often been observed as an enzootic in France and Holland. He mentions fever as being a symptom of the disease, and, of course, jaundice. He lays stress on the swelling of the head, but although he mentions colliquative diarrhoea as being very obvious at one stage of the disease, he does not emphasise it. Indeed, he rather emphasises a constipative stage of the disease. More will be said on this point when we come to deal further on with a disease which he calls cholera of the sheep.

#### Results of Bacteriological Investigation.

I now proceed to detail briefly the results obtained with the material derived from the duodenum of Lamb 1. The contents of the duodenum were diluted in peptone water and plated out on MacConkey lactose-agar. After 24 hours' incubation the plates were seen to contain two types, and two types only, of organisms—namely, a non-lactose fermenter which I shall call B, and a lactose fermenter which I shall call A. Four colonies of the A type were picked off and six of the B type. Both were Gram-negative coliform bacilli, both were slightly motile, while the reaction of the two organisms on various media may be given in tabular form as follows:—

—	(A)	(B)	—	(A)	(B)	—	(A)	(B)
Lactose.	A G	0	Litmus milk.	A C	A	Saltin.	A G	A G
Dulcitate.	A g	A G	Glucose.	A G	A G	Inulin.	0	0
Saccharose.	A G	0	Mannite.	A G	A G	Galactose.	A G	A G
Raffinose.	A G	0	Maltose.	A G	A G	Gelatin.	Growth*	
Sorbitate.	A G	0	Dextrin.	A g	A g	Peptone water.	†	Present.

A = acid formation; G = gas formation; g = small amount of gas formation; C = clot formation; 0 = no change.

\* No liquefaction. † Indol formation.

It will be seen that type A organism is a lactose fermenter of advanced *B. coli* type, while type B organism is a paratyphoid-like organism. In papers about to be published I am submitting evidence which goes to show that type B organism can, and does, mutate into type A organism; that these two organisms, for all practical purposes, are one and the same; and that in consequence the infection of the duodenum in this case was a pure infection with one organism only. The further experimental results, however, recorded in this paper are to be regarded as pertaining only to type B organisms, with which the experiments were performed, although a fair number of experiments have been performed by me with type A organism with results differing, if they differ at all, quantitatively not qualitatively.

*Animal Experiments.*

The next question to be decided was whether the disease described above could be produced in animals.

Sheep were not available, consequently rabbits were used; and as infection of rabbits with other pathogenic organisms of an intestinal type, such as typhoid, had markedly failed when the organisms were administered by the mouth, the cultures here were given intravenously through the ear vein. When the organism was administered thus—speaking always of the non-lactose fermenter—it was seen to be very lethal, and a minimal lethal dose had to be established for working purposes. Working with a sublethal dose, 16 experiments on rabbits were performed, and the clinical symptoms observed, and the pathological and bacteriological findings obtained at various intervals subsequent to injection, will now be briefly described.

With regard to the symptoms produced, the animal became very ill about an hour after injection, and a profuse colliquative diarrhoea commenced which lasted for about 48 hours. Subsequent to this the faeces became oat-shaped, small in size, dark in colour, hard in consistence, and covered in some cases with mucus and blood. A few cases recovered after this, but in most cases the faeces continued more or less of this nature, the animal refused its food, became more and more emaciated, and died, in the more prolonged cases, in three to four weeks.

When an animal was killed after 48 hours the contents of the intestine were observed to be entirely fluid, and there were no faecal pellets in the rectum; the duodenum was markedly inflamed; there were hæmorrhages throughout the liver, and the gall-bladder was distended with pure blood. Pure cultures of the organism injected, without any contamination, were obtained in all such cases from the gall-bladder and duodenum.

If the animal were killed at a later period—say, from a week to three to four weeks after injection—the intestinal and duodenal changes were not so noticeable, the extreme emaciation was very marked, and changes in the liver and gall-bladder were pre-eminent. Thus in some cases there was acute necrosis of a whole lobule of the liver, while in cases not so marked as this there was evidence of a fibrosis round the small bile-ducts, a small-celled infiltration, a fibrosis, and proliferation of the bile capillaries in the portal spaces.\* The gall-bladder showed small-celled infiltration of the submucosa (and in one case ulceration) and fibrous thickening of the walls. The common bile-duct and cystic duct in one case were greatly thickened and greatly dilated. The contents of the gall-bladder, instead of being green and viscid as in the normal condition, were watery-like and turbid, with a white sediment, which in some cases suggested calculus formation.

A pure uncontaminated growth of the organism injected was obtained from the gall-bladder in these cases; in one case after the lapse of four weeks. In all these cases, too, a pure uncontaminated culture of the injected organism was also obtained from the duodenum.

This is a remarkable result, not because the organism was obtained, for the gall-bladder would act as a supply reservoir, but because it was obtained *uncontaminated*, considering that food, containing organisms of all sorts, was being eaten all the time. Certain other observations which I made during the course of the experiment would support the view deducible from this that normally the contents of the duodenum are sterile, at least, as far as growth on MacConkey lactose agar is concerned. On several occasions I made cultures from the duodenums of healthy rabbits, killed for other purposes, and found them sterile. The bile may act as an antiseptic for various organisms, but this can hardly be the case for coliform organisms.

It is to be noted that none of the experimental animals developed jaundice, swelling of the parotid, or gangrene of the ears. This is not surprising, considering the comparative rarity of these conditions in the natural disease among sheep.

A few experiments were performed by me relative to the protective value of a previous intravenous injection, to a similar subsequent inoculation of a much larger dose. The experiments are few in number, but they go to show that a protection is developed in this way. Thus, rabbits so treated withstood a subsequent intravenous injection of three to six times the original dose (which was just a subminimal lethal one) and showed practically no symptoms.

*Provisional Results of Inquiry.*

One may provisionally here sum up the finding so far in connexion with the disease. It would appear that the disease

in the sheep is primarily a duodenitis characterised by a marked colliquative diarrhoea and which has as sequelæ the production of jaundice, swelling in the parotid region, and local gangrene of the ears. Evidence has been adduced by me from the bacteriological examination of the sheep and from experimental work on rabbits, that a bacillus of the paratyphoid group has strong claims to be considered as causal. This work, of course, will have to be, and is being as opportunity arises, extended especially in the direction of further examination of diseased sheep, the production of the disease in healthy sheep with the organism in question, and the development of further prophylactic measures, vaccinal and otherwise.

*Comparison of Certain Symptoms in Cholera in Man.*

I have already alluded in passing to the resemblance of this disease to cholera in human beings. I was so struck with the marked resemblance of the colliquative diarrhoea of this disease to that of cholera, that I began to investigate whether the other symptoms observable in this disease had been recorded in the case of cholera.

In this connexion it is interesting to note that authorities on the subject, such as Manson<sup>2</sup> and Leonard Rogers,<sup>3</sup> state that jaundice, parotitis, and gangrene of extremities, such as the nose, the penis, the scrotum, the fingers, and toes, &c., are among the sequelæ of cholera in the human subject.

Further, Greig, in a series of papers,<sup>4,5</sup> has brought to light many facts in relation to the pathology of the liver in cholera. He quotes Kntescha as having examined post mortem 109 cholera cases and found the cholera vibrio in the gall-bladder of 49 cases, while in 10 per cent. of these 49 cases its presence was associated with marked pathological changes in the biliary passages. Again, he quotes Bruloff as having found the cholera vibrio in the gall-bladder of 76 per cent. of his cases. Greig himself, in an examination of 271 fatal cases of cholera, found the cholera vibrio in the gall-bladder of 80, and associated with distinct pathological changes in 12 out of these 80 cases. His histological findings in the gall-bladder and liver in these cases, as also in the gall-bladders and livers of his experimental rabbits which he injected intravenously with the cholera vibrio, are practically identical with what I have described above in this disease.

The further point from a pathological point of view in the comparison of the two diseases is that cholera is primarily a duodenitis (Leonard Rogers, loc. cit.). This raises the further interesting question of the cause of the colliquative diarrhoea in the two cases.

*Causation of the Colliquative Diarrhoea.*

It may be due to the same or a similar specific cathartic toxin in the two causal organisms, but it seems to me that it is more likely that it is due to a toxin (much less specifically and drastically cathartic and which occurs in very many intestinal organisms besides the two mentioned), acting on a *specific locus* of the intestinal tract. The emphasis of the specificity is rather on this locus—the duodenum—than on the toxin.

I have had in progress, though the progress has been interrupted latterly, since 1915 some experiments on the pharmacological action of emulsions of various intestinal pathogenic organisms, such as typhoid, paratyphoid, the dysenteries, &c. The organisms were killed by heat and the emulsions so prepared were injected intravenously into rabbits. In every case tested, with the exception of Shiga's dysentery bacillus, colliquative diarrhoea was produced, and post mortem the duodenum was found to be markedly congested and dotted over with hæmorrhages. No diarrhoea and no duodenal change was produced, however, when these emulsions were injected subcutaneously or intraperitoneally. Catharsis, again, is not produced by the subcutaneous injection of *V. cholerae* (Manson).

My reading of these results is that the toxic material was excreted by the bile and, arriving at the duodenum first, exerted its action there and produced what one may call the duodenal result—namely, colliquative diarrhoea. That this same result is produced in cholera and in the disease we are dealing with here, in my opinion, is due to the fact that their causal organisms grow in the duodenum and produce their effects from there; while the fact that colliquative diarrhoea, which is absent in the natural diseases such as typhoid, can yet be produced on intravenous injection of the

\* The details of the changes are at present the subject of further investigation by Professor Beattie and myself.

causal organisms, to my mind is explained similarly, in that the site of growth of these organisms in the natural disease is not the duodenum, but farther down.

Other evidence of a specific duodenal action lies in the fact that in both the diseases we are dealing with here, cholera and the sheep disease, parotitis is a marked sequel, while in medicine generally it has long been recognised that various grave affections of the duodenum give rise to parotitis. It is highly speculative, of course, but it is permissible to wonder if mumps may not primarily be a duodenal affection.

#### *The Overlooking in the Disease of the Diarrhoea.*

The next point I will deal with is the question as to how the diarrhoea so evident in the disease has up to the present time been overlooked.

May describes at another part of his book (p. 31) as an entirely different disease a condition in sheep which he calls "the cholera-like disease of sheep." He himself had not seen the disease, and he is quoting from an article in the *Journal de Médecine de Bruxelles*, September, 1854. The disease was a very fatal one and was characterised by colliquative diarrhoea and swelling of the parotid glands. The European epidemic of cholera, 1851-55, was raging at the time, and the writer of the article, a Dr. Liegen, suggested a relation between the two conditions.

Now diarrhoea in sheep is almost, one might say, an everyday occurrence, even although it may not be of a colliquative nature, and no special importance is attached to it by shepherds. Familiarity, however, with the diarrhoea of cholera, as happened in this case, and as might have happened in Scotland had cholera epidemics been more frequent, and had they synchronised, as in this case, with this disease in sheep, might have led shepherds and others to recognise more fully its exact nature and ascribe to it, by name or otherwise, the importance it undoubtedly has in a disease up to now designated only by its sequelæ.

#### *Epidemic Jaundice.*

In conclusion, a further point needs to be discussed. Attention has been drawn, owing to the war, to the prevalence of a type of jaundice among the Balkan troops.

Sarrhailé and Clunet,<sup>7</sup> in dealing with an epidemic of this sort, came to the conclusion that the epidemic of jaundice at Gallipoli was a manifestation of paratyphoid A fever; C. J. Martin<sup>8</sup> opposes this view on bacteriological grounds, and suggests, from histological examination of livers of affected cases, that the infectious jaundice of Gallipoli, although much milder, presented analogies to the severer form, *Spirochaetosis Ictero-hæmorrhagica*, and believes that the symptomatology and morbid histology are consistent with the view that it is primarily a systemic infection. Hurst<sup>9</sup> and Wilcox<sup>10</sup> believe that the condition is of the nature of a catarrhal jaundice spreading from the duodenum.

Cantacuzène<sup>11</sup> describes the disease as it occurred in Roumania. It was of a very mild type, and in the rare cases which died there was fatty infiltration of the liver due, in his opinion, to primary angiocholitis of the intralobular biliary canaliculi. The search for spirochaetes by the injection of guinea-pigs was negative. Blood culture was positive in one-third of the cases and yielded atypical paratyphoid bacilli resembling somewhat paratyphoid B. He records experimental production of the disease by people voluntarily swallowing cultures of the organism. He regards this organism as the cause of the disease.

Hategan,<sup>12</sup> in an outbreak of epidemic jaundice, obtained, with the duodenal sound, bile which showed in 65 per cent. of the cases on first examination a very actively motile bacillus which he thinks is the cause of the disease. Meyer<sup>13</sup> records an epidemic of jaundice in the Waziristan Field Force, and comes to the conclusion, on rather insufficient evidence it would appear, however, that an organism of the enteric group, probably closely allied to the paratyphoid, might be the causative agent.

The question of the cause of this disease cannot be said to be settled and, on the whole, the evidence so far adduced would appear to be against the disease being of the nature of a catarrhal jaundice.

In a previous paper<sup>14</sup> I suggested that head-grit might be a hæmorrhagic septicæmia manifestation. This I did because from the head of a lamb, sent in to me diagnosed as head-grit, I obtained a pure culture of the *B. bipolaris septicus*. As swelling of the head is also one of the marked symptoms

of hæmorrhagic septicæmia I concluded that this was the nature of the disease in question here. Evidently the diagnosis, for which I was not responsible, as so often happens, though unavoidable under the circumstances, was wrong, and I was in consequence misled.

This paper was first submitted for publication six months ago.

## AURAL SUPPURATION IN EARLY CHILDHOOD:

### ITS PREVENTION AND TREATMENT.

BY DOUGLAS GUTHRIE, M.D., F.R.C.S. EDIN.,

INTERIM SURGEON TO THE EAR AND THROAT DEPARTMENT, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH, AND SURGEON TO THE EDINBURGH EAR AND THROAT INFIRMARY.

In every clinic devoted to the ear and throat diseases of childhood two affections command the attention to such an extent that all others fade into insignificance—viz., (1) tonsil-adenoid disease, and (2) middle-ear suppuration. 90 per cent. of the work comes under one or other of those headings. But while parents and practitioners are fully aware of the ill-effects wrought by lymphoid enlargements about the throat and of the improvement, often quite dramatic, which follows their removal, suppurating ears are apt to be overlooked and neglected.

Middle-ear suppuration is not in itself a fatal disease; indeed, the majority of cases tend towards natural cure, but it brings many evils in its train. The constant swallowing of septic material causes ill-health and sometimes enteritis, meningitis is not rare as a sequel of otitis, whilst the destruction and cicatrization resulting from the inflammatory process may so damage the delicate ear mechanism as to lead to deafness, which to a young child commencing its education is a severe handicap. Even though the cure of an otitis in childhood appears complete, it is conceivable that some of the deafness of later life—for example, certain cases of otosclerosis—may be traceable to aural suppuration during early years.

Text-books give scant information on suppurative otitis media as it affects children. True, the disease in a child of school age may closely resemble the adult type, but a glance at the temporal bone of an infant suffices to show the extent to which pathology may be modified and altered by anatomy.

#### *Anatomical Data.*

If we look at the base of a foetal skull, such as is used for obstetrical demonstrations, we see that the most prominent features, next to the foramen magnum, are the large tympanic membranes, lying almost horizontally. There is no osseous meatus, and the drum lies so obliquely as to be practically in the same continuous plane as the upper wall of the membranous meatus. The mastoid process, as the specimen shows, is as yet undeveloped, but the mastoid antrum is relatively large, is well drained by a roomy aditus, is close to the surface of the skull, and lies higher in relation to the middle ear than does the adult antrum. The Eustachian tube is relatively shorter, wider, and more horizontal than it is in the adult, so that it acts as a good drain, though, on the other hand, infection of the middle ear from the nasopharynx is favoured. A final anatomical, or rather histological, fact of importance is the occasional presence in the middle ear or antrum of a network of embryonic tissue. Usually this completely disappears before birth, but at times it persists in the antrum or attic during the first few months of extra-uterine life, and in such cases the presence of so delicate and vulnerable a structure may render its possessor peculiarly liable to otitis media.

#### *Otitis Media in the Infant.*

As a matter of fact, aural suppuration occurs with extreme frequency during the first year of life. The results recorded

in various papers on the subject by eight different observers who examined the ears at a series of post-mortems on infants show that otitis was present, on an average, in 82 per cent. It has been doubted whether the presence of pus in the middle ear after death in so large a percentage of cases was really pathological. Indeed, Aschoff regarded it as a "foreign body" suppuration, resulting from the presence of vernix, meconium, &c., which had entered by way of the Eustachian tube. While this explanation may hold good for new-born infants, the pus has seldom been found sterile, and bacteriological investigations have only confirmed the extraordinary prevalence of the disease. Most of the cases yield the pneumococcus, while next in frequency comes the streptococcus, the latter giving rise to a more severe infection, sometimes complicated by mastoiditis.

The close connexion between otitis and pneumonia has often been remarked, and it is said that the middle ear is infected in every fatal case of infantile pneumonia. The commonest cause, however, of otitis in infants is the ordinary cold, which is a serious disease in early life. The nasal passage of a baby is easily blocked, feeding is rendered difficult, and infected secretions are readily forced into the middle ear.

*Symptoms.*—Among all the diseases of children probably none is so frequently overlooked as otitis media. Before the occurrence of perforation and consequent appearance of pus in the meatus the diagnosis is no easy matter.

The ears should be examined in all infants who suffer from fever of obscure causation. The temperature may be high, or it may not rise above 100°; and in the latter case, as Still has pointed out, it is apt to continue even after the inflammation has subsided. Pain, as evidenced by continuous crying, restlessness and sleeplessness, and boring of the head into the pillow are often noted, while the appearance of head-retraction, vomiting, and convulsions may lead one to suspect meningitis, until, with the occurrence of perforation, the true nature of the case is revealed. Pain is not constant, however, and may sometimes be altogether absent. In the average case the drum perforates in three or four days, with prompt relief of all symptoms. At first the pus is profuse, but later it becomes thin and scanty, and as a rule the ear is dry within two or three weeks.

Unfortunately, otoscopic examination does not always assist us to diagnose otitis prior to perforation. The tympanic membrane may, indeed, appear normal if the stress of the disease has fallen upon other parts of the middle ear, and such cases are very deceptive. On the other hand, a red and bulging drum will often betray the condition, though we must remember that in a crying infant the normal drum appears red. In examining the infant's ear remember the obliquity of the drum. The meatus is a mere slit, whose walls must be separated by pulling the auricle downwards. The use of a speculum with an obliquely cut end and a collar to give a good grip in manipulation may assist one to secure a glimpse of the drum, and a fleeting glimpse is often the best obtainable.

Considering the frequency of otitis in infants, mastoiditis is not a very common complication. When it does occur, the thin outer wall of the antrum breaks down, and a subperiosteal abscess forms above and behind the ear, causing considerable downward and forward displacement of the auricle.

*Treatment.*—In the early stages of otitis, dry heat and the use of the well-known cocaine, carbolie, and glycerine drops will relieve symptoms, but surgical treatment is more effective, and the small operation of paracentesis tympani might with advantage be performed more frequently. The incision should divide the posterior part of the drum from below upwards, and should be continued a little way along the inflamed meatal wall. General anaesthesia is advisable. The small clot which forms over the incision must be syringed out a few minutes later, as it is apt to impede drainage. Pus may not appear at once, but the flow will become established within a couple of days.

#### *Tuberculosis of the Middle Ear.*

This disease is not uncommon in the infant, though it becomes less and less frequent as age advances. In a series of 150 consecutive cases of chronic middle-ear suppuration in children under ten years of age attending the Royal Hospital for Sick Children, 13 cases were of definitely

tuberculous origin. In all of the 13 cases save one, a child aged 3, the disease commenced during the first year of life.

As regards symptoms, all cases were characterised by a painless and gradual onset, and all showed enlarged glands around the ear. Facial paralysis was noted in 7 cases, while in 3 cases a mastoid abscess had formed and ruptured, causing a mastoid fistula.

The ætiology of aural tuberculosis is most important from a public health point of view, for there is little doubt that the infection is milk-borne and reaches the ear by way of the Eustachian tube. Ten of my patients were bottle-fed, and only in one instance was the milk boiled.

The treatment of the condition consists in a very radical mastoid operation. This was carried out in 9 cases, in all of which extensive bone necrosis was found, and microscopic examination of the granulations confirmed the diagnosis. Six did well and 3 died, one of meningitis a week after operation, and the other two several months later, of pneumonia and convulsions respectively.

#### *Otitis Media in Older Children.*

Let us now consider the problem of aural suppuration in older children. At the age of 2 the mastoid process is already developed, and the disease tends more and more to approach the adult type. Acute inflammation is common, but the important lesion, the disease which destroys hearing and yet goes untreated in so many cases, is chronic suppurative otitis media, or for short, aural suppuration. Even in the framing of child welfare schemes the prime importance of this disease is not recognised, while the provision of skilled aural treatment in fever hospitals remains an urgent necessity. The ears of the school child are nowadays well inspected and treated, but the child of more tender years is apt to be forgotten.

Indeed, a recent writer goes so far as to say that "there is little ear disease amongst children until the beginning of the school period." Surprised by this statement, I looked over my records of cases of aural suppuration in children, and found that of 145 patients no less than 95 were under the age of 5 years. It would therefore appear that ear disease is by no means uncommon in children under school age.

School medical inspection reports in Scotland show that of school entrants 1.3 per cent. have discharging ears. The figures range from 0.5 per cent. in Linlithgow county to 1.9 per cent. in the town of Stirling, but rural and urban populations appear to suffer with equal frequency. These estimates are probably low, as the ears may not be discharging at the time of examination. How familiar is the statement that "the ears have been running for months (or years) off and on."

#### *Ætiology.*

Now what is the cause of all this ear disease, and how may it be prevented? In 130 cases of aural suppuration in children aged 1 to 10 years, I have on 66 occasions obtained from the mother a statement as to the supposed cause, with the following result:—

Measles ... .. 40 cases (31 %)	Whooping-cough 5 cases (4 %)
Scarlet fever ... 8 " (6 %)	Injury (?) ... 3 " (2 %)
Pneumonia ... 8 " (6 %)	Diphtheria ... 2 " (1.5 %)

The most striking fact revealed by the table is the high percentage of measles cases. It may be mentioned that these figures were drawn from two different years, so that they are not swelled by any particular epidemic. The small number of scarlet fever cases arises from the fact that two-thirds of the patients had not yet reached the age at which scarlet fever attains its maximum incidence.

Downe, who investigated the cause of otitis in 500 cases, found 26 per cent. due to measles and 12 per cent. due to scarlet fever. Scarlet fever is well known for its destructive effects on the ear, but on the whole it is well treated, as it is a notifiable and a hospital disease. Measles, on the other hand, is not notifiable, is treated at home, and is too often regarded as a trivial complaint. In reality, it is a more dangerous and disabling disease than scarlet fever, and the importance of measles, as a cause of chronic middle-ear suppuration, cannot be too strongly emphasised. All measures for the prevention of measles, whether by improved housing and greater cleanliness, by prompt isolation and more careful nursing, or by better treatment during the convalescent stage, will go far towards lessening

the tendency to aural complications and reducing the number of cases of preventable deafness in later life.

A second factor in the aetiology of aural suppuration is perhaps the most important factor of all. The great majority of children who suffer from chronic otitis are also sufferers from adenoids, and the septic infection of those adenoids are not only the cause of the otitis, but also the cause of its chronicity. The adenoid operation, therefore, has an important place in the prophylaxis as well as in the treatment of ear suppuration. As a portal of infection, the pharyngeal tonsil is second to none. Here enter measles, meningitis, and many another ill, and infection may readily pass from septic adenoids, along the Eustachian tube to the middle ear.

Measles and adenoids, then, are the two principal causes of aural suppuration in young children, and merit even greater attention than has hitherto been accorded to them.

#### *Treatment.*

The following scheme of treatment may be a useful guide in average cases: (1) cleansing and antiseptics; (2) removal of adenoids; (3) conservative operation; and (4) radical operation.

(1) and (2) will cure the majority of cases. After having tried many methods, I now advise the mother to make some mops with matches and cotton-wool, and with these to mop out the ear until dry; then to instil a few drops of peroxide of hydrogen and mop out once more until dry. This is to be done twice a day. Syringing, in unskilled hands, is worse than useless, and, indeed, I have known ears to cease discharging when the only advice was to stop syringing. The mopping method is a much more effective measure. As the discharge lessens, rectified spirit may, with advantage, be combined with the peroxide.

The importance of adenoids has already been noted. Large, firm masses may be present, but more frequently a small block of friable and pus-soaked tissue is removed at the operation. Should the removal of adenoids, and two or three months of systematic "mopping and drops," fail to effect improvement, operative methods must be considered.

The radical mastoid operation is seldom indicated in childhood and should only be performed in carefully selected cases—e.g., cholesteatoma, necrosis of ossicles, &c. One naturally hesitates to perform, upon a small child, an operation whose effects upon the sense of hearing cannot be foretold.

For this reason the so-called "conservative" mastoid operation (modified radical) should be chosen whenever possible. Into the details of the operation I do not propose to enter here, but shall merely enumerate its various stages—the opening of the antrum, the removal of the greater part of the posterior wall of the bony meatus, the curetting and clearing of the aditus (for this a bayonet-shaped dental excavator is most useful), the construction of a wide meatal flap, and the treatment of the bone cavity with bipp, which gives such excellent results in mastoid surgery. By this operation drainage is provided, while the drum and ossicles are left untouched, and the middle ear may recover, with full possession of its functions.

I lately had the opportunity of examining six cases, upon all of which I had performed the operation over two years ago. The ear was dry in five cases, and in all cases hearing was good (whisper at 6 feet).

**LEICESTER ROYAL INFIRMARY.**—On the promotion of Dr. T. V. Crosby to be honorary physician to the infirmary two vacancies were offered for assistant physicians, and to these Dr. J. D. Slight and Dr. Arthur Foster have been appointed. During the war Dr. Slight has been in charge of medical patients, officers as well as other ranks, at the 5th Northern General Hospital, and has also acted as temporary physician to the Royal Infirmary. Dr. Foster has been in charge of medical beds at the same military hospital. Mr. R. S. Lawson was at the same time appointed assistant surgeon. Mr. Lawson has been lecturer in anatomy at Edinburgh University, and acted as assistant lecturer and demonstrator in the pathological department there. During the war he was operating surgeon at the Royal Naval Hospital, Chatham, and on a hospital ship, and since demobilisation has been doing surgical work at Alder Hey Military Orthopaedic Hospital.

#### A NOTE ON

### PROPHYLACTIC QUININE IN MALARIA.

By A. H. GOSSE, M.D. CANTAB., M.R.C.P. LOND.,

BREVET MAJOR, R.A.M.C. (T.F.).

It was with an unbiassed view of its value or otherwise that the following investigations into the use of prophylactic quinine in malaria in two units of the Mesopotamian Expeditionary Force were carried out, and as they led to definite opinions they are now reported.

#### *The Investigation Described.*

A medical unit to look after a thousand hospital or convalescent patients was located at Mohammerah, some 25 miles from Basrah, with little or no opportunity for the personnel to visit other units, so that any infection by the malarial parasite was due to the conditions in the camp. As these conditions seemed to indicate that it was a suitable opportunity an investigation was undertaken. The troops permanently posted there consisted of three officers and about 30 N.C.O.'s and men, who had only been one month in the country, and had come direct from England. During this month one man had contracted malaria while in Basrah, and he was excluded from the investigation. None of the others had ever had malaria. No quinine was issued to or taken by any of them, as I explained to them that as it was a new camp, and the presence of mosquitoes infected by the malarial parasite was doubtful, experience alone would show whether it was necessary to take quinine or not, as every anopheles is not necessarily a carrier of malaria. If any of us became infected the administration of quinine would be reconsidered. For nine months, from September, 1916, to June, 1917, no quinine was taken and no malaria occurred. Towards the end of June two of the nursing orderlies reported sick with high fever on the same day, but it was not till four days later that a diagnosis of malaria was made. On this day a warrant officer reported sick and a blood film showed B.T. parasites present. Quinine sulphate, gr. v., in a mixture daily was ordered for the remaining 30 as a prophylactic measure. A list of their names was made and each dose taken was recorded. The men were told that an investigation was being carried out and they showed their interest by their methodical attendance at the dispensary to take quinine without any attempt to evade it. Three days later one of the men went sick and was also found to have malaria, but he must have been infected some ten days at least before quinine was started and 5 gr. daily was not sufficient to stop an attack. *During the next three months no further case of malaria occurred.* Major S. R. Christophers, I.M.S., visited the camp during this period to make an examination for anopheles in the area, and in the first tent found over a dozen. The value of the administration of prophylactic quinine in this camp seemed to be demonstrated.

I was then transferred for duty to a hospital five miles from Basrah. The female nursing staff of this hospital consisted of nine nursing sisters, none of whom had had malaria, though several of the orderlies were then sick with it. I advised them all to take quinine, but emphasised the importance I attached to being informed beforehand of the names of those who would take it regularly. The matron very kindly gave every assistance and the quinine mixture was handed round at their mess, where it was taken regularly by five of them, but the other four declined it, and these I regarded as controls. The five taking quinine did not develop malaria then or at any time while they were in Mesopotamia. Of the other four, two of them had malaria with parasites demonstrated in blood films within a month.

Shortly afterwards four new sisters were added to the nursing staff. Two of them took quinine from the first day, while two others preferred not to take it, and were therefore regarded as further controls. In less than three weeks both the controls developed a temperature on the same day, and parasites were found in their blood. The two who took quinine did not develop malaria. Experiences such as these make it impossible to accept the view that prophylactic quinine is useless at all times.

#### *Remarks.*

Far more elaborate investigations than these have been frequently reported, and still the opinion for or against

prophylactic quinine is divided. Why, then, this apparently conflicting evidence? The work of these investigators must be accepted on both sides. It appears, then, that the solution can only lie in the discovery of the variable conditions under which the conflicting experiences have been obtained. To explain my meaning, let me refer to the opposing views which in the past have been held over the value of digitalis in heart disease. It is now known that the beneficial effects are exhibited in patients with the rapid pulse-rate of auricular fibrillation or auricular flutter, but has practically no effect on other cardiac conditions. The solution, then, lay in the discovery of the variable conditions under which the conflicting experiences had been obtained. What are these variable conditions in prophylactic quinine? May it be in the variable amount of the dose at the time of infection, or, in other words, in the variable number of bites received in 24 hours from infective anopheles?

Mesopotamia is not a very malarious country. Death from uncomplicated malaria is rare. The mortality is larger when complicated by heat stroke. The incidence of malaria is not high when compared with a badly malarious country like Northern Persia or Salonica, where prophylactic quinine is said to be almost useless. The conditions under which prophylactic quinine was demonstrated to be so beneficial in the above investigations was in a country where, as a rule, the infection was not severe and therefore probably the infecting dose was small—i.e., the numbers of bites from infective anopheles was small in any one day. It is suggested that the value of prophylactic quinine varies, and the prophylactic dose should be in direct proportion to the severity of the infection in any given area. There should be an optimum prophylactic dose for that area. The cases receiving an exceptionally large number of infective bites will still develop malaria, but the rest will be protected. In a very malarious country, when one is frequently bitten in the 24 hours by infective mosquitoes, gr. v., gr. x., or even larger doses may be insufficient to kill the parasite in all but a very few cases, and then prophylactic quinine might be regarded as useless.

#### Conclusion.

Prophylactic quinine in Mesopotamia is of the greatest benefit, but in certain other places it is almost, if not quite, useless, and it may be that, provided the dose necessary is not too high for regular administration, an optimum prophylactic dose will be demonstrated for every malarious area, varying even with the seasons and indicated perhaps by the rising or falling incidence of the disease.

## X RAYS IN THE TREATMENT OF CERTAIN FORMS OF DYSMENORRHOEA:

### A PLEA FOR THEIR MORE EXTENSIVE USE.

By FRANCIS HERNAMAN-JOHNSON, M.D. ABERD.,

RADIOLOGIST TO THE FRENCH HOSPITAL; PHYSICIAN TO THE X RAY DEPARTMENT, THE MARGARET-STREET HOSPITAL FOR CONSUMPTION, ETC.

THE object of this article is to call attention to certain methods of treatment which often succeed in cases of menstrual disturbance, when more orthodox measures, medical and surgical, have failed. I hasten to say that certain conditions should be fulfilled before any case of such a nature is undertaken by the radiologist. They are: (1) treatment by ordinary medical methods (drugs, regulation of way of living, &c.) should have a fair trial—by this is meant a matter of a few months; (2) surgical investigation must be made to exclude any gross deformity, and any minor surgical procedure not dangerous to life—e.g., dilatation of the cervix—tried if it seems indicated.

By this I do not mean to convey that no cases presenting any abnormality of an organic nature should be accepted. Cases in which serious malposition of the uterus was found and surgically corrected have failed to benefit, but have subsequently been cured by X rays. The presence of a certain amount of congestion in the ovaries and uterus is also not a bar to success; but it is important that the radiologist should know of any condition which may, should he fail, require surgical interference. Cases in which the uterine contents are septic—as after abortion—or where large fibroids are present, are obviously suitable for surgical treatment only. On the other hand, there

are those in which nothing in the nature of a possible organic cause can be demonstrated. But, inevitably, there must be borderline cases in which opinions will differ as to what treatment should be followed. In making a decision it should be remembered that X ray treatment can be conducted without risk; if it fails, surgery can still be resorted to. But operations for straightening out uterine kinks are not wholly free from danger, and an excised ovary cannot be replaced.

#### Characteristics of a Suitable Case.

The type of case most suitable for X rays presents the following characteristics: (a) It is free from gross organic lesions. (b) There is excessive and prolonged bleeding at the menstrual periods, which follow one another with undue rapidity. (c) There is more or less pain of the usual menstrual type, and frequently headache and mental depression. (d) Owing to the excessive loss of blood and the shortness of the intervals the patient never really feels fit.

Cases conforming closely to the above type yield to X ray treatment with great regularity. A wide cone of rays is used, filtered through 3 mm. of aluminium, so that the ovaries and uterus receive radiations more or less equally at each sitting. The external genitals are protected by ray-proof material to prevent any possibility of temporary epilation. These patients are rarely able to attend for treatment for much more than two weeks out of four; and endeavour should be made to give at least seven sittings during each interval. The first period after starting treatment is usually worse, and the second may be little better. But if the treatment is going to succeed, the third should show distinct improvement. If it does not, ultimate success is unlikely. When improvement is obtained, X rays are omitted during the fourth interval, and a final course given during the fifth.

#### Objections to the Treatment.

Two objections have been raised against this form of treatment: (1) that there is risk of sterilisation; (2) that the integrity of the skin is endangered. The one question is in reality bound up with the other. It is practically impossible permanently to sterilise a woman below 40 without injury to the skin. In the literature on the X ray treatment of uterine fibroids great stress has been laid upon a technique which will produce sterilisation, and in consequence the method has not been recommended for patients who have not completed their fourth decade. But in dealing with young subjects who suffer from menstrual disturbance no attempt is made to carry the dosage beyond what is necessary to restrain excessive ovarian function. This statement implies a theory as to the cause of the type of dysmenorrhoea under discussion. The theory is that just as excessive thyroid—or possibly thyroid and thymus—action is the immediate cause of the symptom-complex known as Graves's disease, so does excess of ovarian hormone produce what the present writer has ventured to call the "ovarian syndrome": excessive bleeding, prolonged periods, diminished intervals, headache, and depression. In exophthalmic goitre the thyroid can be "tamed" without in any way interfering with its normal function. In a similar way the ovary, regarded as a ductless gland, can be restrained from excessive exuberance by comparatively small doses of X rays. It was proposed some years ago by a well-known surgeon that portions of the ovaries should be removed in such cases. This procedure would, of course, be exactly on a par with partial thyroidectomy for Graves's disease, and could only be regarded as justifiable if all other measures failed. Also, as regards X rays, their effect upon low forms of inflammation in general must not be forgotten. In chronic colitis, for instance, their beneficial effects are well established, and therefore the lining of the uterus, if congested, is in all probability directly benefited by their application.

#### Effects on the Skin.

As to visible effects on the skin, a sun-burnt appearance is generally produced about the end of the second course. There should be no redness or tenderness; at the most a slight itching at night, which is readily relieved by cold cream. This browning occurs only when small, graduated doses are given, and appears to be protective.<sup>1</sup>

<sup>1</sup> I have found that in treating cancer once this browning is produced very large doses are tolerated for months and even years without any breaking down.

With the small dosage necessary in dysmenorrhœa cases, the brown layer begins to peel off in about one month after the cessation of treatment, leaving a perfectly healthy skin surface. The skin is fully fit to stand operation, should this be necessary, within two months.

#### *Danger of Faulty Technique.*

That great harm can be done by faulty technique must be admitted; but this can be said of most modern methods of treatment. The risk in skilled hands is practically nil. And it must be remembered that—if the conditions stated at the beginning of this article have been fulfilled—either there is no alternative, or the alternative is a major operation.

To the majority of such patients life is literally not worth living, and I personally have found no class of sufferers so pathetically grateful for relief as women thus afflicted. It is essentially a disorder of young women, and ruins the best years of their life, often preventing marriage; or, what is worse, making it a failure.

As to choice of cases, the more nearly one approaches to the type described in the early part of this paper, the more likely is it to benefit by X ray treatment. When pain is prominent rather than loss of blood, cure is less probable, but a trial should be made.

#### *Recent Cases.*

The present writer first referred to this subject in an article published some years ago, in which details of several cases were given.<sup>2</sup> Two more recent ones are quoted below.

L. B., school-teacher, 30. First seen January, 1918. All her life had been troubled by excessive loss at periods. Of late years the condition had become steadily worse. Periods lasted ten days, and the free interval was less than a fortnight. There was a good deal of pain and headache at the time, and 2-3 days had to be spent in bed. She was in danger of losing her position and was in a very depressed state, threatening suicide. She had had prolonged treatment from her medical attendant and was certified by a gynaecologist to be apparently free from organic disease. X ray treatment at first aggravated the condition, and the interval succeeding the commencement of treatment was so short that X ray dosage was continued through a part of the second period—a departure from the usual procedure. The free period following lasted three weeks, and the succeeding period—the third after the commencement of treatment—was almost normal. A complete cure seems to have resulted, as the patient wrote in December, 1918 (seven months after stopping all treatment), to say that she was quite well.

The above case is typical of those in which a large measure of success may reasonably be expected. In one such as the following less confidence can be expressed.

C. M., 28, spinster. Had suffered since the age of 14 from painful menstrual periods lasting 6-7 days. Flow somewhat greater than normal. Headache severe for 3-4 days at the time of periods. Year by year the condition had become worse. General health in intervals indifferent, and patient was unable to follow any regular occupation. The uterus and both ovaries were slightly enlarged and tender to palpation. The girl was very miserable, and a gynaecological surgeon suggested complete removal of the organs if no other means of relief could be found. As a final resort before operation it was decided to try X rays. The second period after the commencement of treatment was considerably better, in so much that the bleeding was less and that it lasted only five days. Pain also was not so violent. Two more "interval courses" of X rays were given, but no further improvement occurred, and, in view of the possible final necessity for operation, it was not considered desirable to push the treatment. Result: Periods reduced to five days instead of 6-7. Flow normal. Pain more bearable. General health improved. Patient writes three months after cessation of treatment to say that, on the whole, she remains much better than before she had X rays.

In the above instance X ray treatment succeeded only to a limited degree, but it enabled the patient to avoid a serious and mutilating operation, at least for the time. I am not to be taken as opposing the operation of pan-hysterectomy in intractable cases of dysmenorrhœa, provided every other possible means of relief have been tried without success, but X rays should always be remembered as among the most powerful of these means.

The radiologist, holding, as it were, a position midway between that of the physician and the surgeon, has no need to encroach upon the domain of either. The patient with

dysmenorrhœa should first receive medical treatment—the term "medical" being used in its more limited sense. If this fails, it should be ascertained whether there is any recognised surgical cause for the trouble, such as a contracted os, or whether any condition exists dangerous to life—e.g., septic endometritis, large fibroid, uterine cancer, &c. Failing the presence of any of the above, X rays should be tried before major surgery is resorted to.

The vexed question as to the treatment of uterine fibroids I do not purpose entering on here, except to say that *small* fibroids associated with excessive bleeding at the menstrual periods, but not in the intervals, can be successfully dealt with by X rays in women near the menopause.

Harley-street, W.

## IODIDES AND THE THYROID.<sup>1</sup>

BY FRED RANSOM, M.D. EDIN.,

READER IN PHARMACOLOGY IN THE UNIVERSITY OF LONDON.

THE specific relationship between the thyroid gland and iodine was first pointed out by Baumann, who discovered that the normal thyroid contains a considerable amount of iodine in organic combination. Iodine is a frequent constituent of cells generally, but the thyroid contains relatively 8-10 times more than any other organ.

Baumann obtained from the thyroid by a somewhat drastic means a substance which he believed to be the active principle called iodothyron, and looking upon it as the cause of the remarkable effects upon metabolism. Oswald has, however, shown that iodothyron is an artificial product, and that its mother substance is an iodised protein, iodothyeoglobulin, from which iodothyron can only be obtained by breaking up the protein molecule.

An extract of the gland made with physiological salt solution contains all the iodine-containing substance, and gives relief in hypothyroidism; but so do various organic and inorganic preparations of iodine, though to a less degree.

#### *Considerations as to the Active Principle of the Gland.*

Are we, then, entitled to consider that iodine is the active principle of the gland? This theory has been advocated by Swingle, who considers that the iodine plays the part of an hormone, but before accepting it certain points require consideration; the presence of iodine in the thyroid is no proof that the activity of the organ is dependent upon its iodine-content, for one function of the thyroid may be to absorb iodine, another to provide a specific internal secretion. Even the fact that iodine is specifically absorbed by the thyroid, and perhaps stimulates secretion, does not prove that iodothyeoglobulin constitutes the internal secretion of the gland. Carlson and Woelfel failed to find iodine in the lymph flowing out of the thyroid. Moreover, the iodine-content of the thyroid is subject to much variation and is greatly influenced by the amount of iodine in the food. The thyroid of carnivora contains little or even no iodine; the amount of iodine is greatest in herbivora, omnivora take a middle place. The thyroid of dogs can be made iodine-free by feeding on an exclusively flesh diet, and still the functions of the gland remain unimpaired. The foetal thyroid and the thyroids of newly born infants contain no iodine, yet in sucking animals thyroidectomy, after removal from the mother, produces its characteristic effects.

The iodine-content of the human thyroid is very variable; Jolin, in extensive investigations in Sweden, found these variations so great that he regards the iodine as of quite secondary importance; he was also unable to detect any connexion between iodine-content and health. Abelin found that a thyroid extract containing much iodine did not differ in activity from one containing little. During the administration of an iodide the iodine-content of the gland may rise to 4-5 times the average normal, and yet in the treatment of cretinism or myxoedema iodides are not so successful as is the taking of the gland itself. In view of these facts it appears at least improbable that the iodine plays an important primary rôle in the activity of the internal secretion of the thyroid.

Is, then, the active principle likely to be a protein? There are several facts which tell against such a

<sup>2</sup> Practitioner, vol. xcii., p. 716.

<sup>1</sup> Abstract of a post-graduate lecture delivered at the London (R.F.H.) School of Medicine for Women.

hypothesis. Abderhalden and also Herzfeld and Klinger got characteristic effects with protein-free extracts of thyroid. Abelin found that thyreoglandol, a protein and lipid-free preparation, has the same effect on metabolism as the gland itself; indeed, the efficacy of the *per os* treatment with the dried gland would seem to indicate that the active principle is not a protein. An iodised protein which v. Fuerth employed was split up in the cat's intestine so that iodine appeared in the cells of the gut wall and in the blood, not as iodised albumin or peptone, but in inorganic form. Abelin considers it likely that the active principle of the thyroid is formed from protein in the cell metabolism of the gland, much as adrenalin arises from the protein of the adrenals. The investigations of Kendall go a long way to confirm this opinion, for he has obtained from thyroid a crystalline body of definite chemical constitution to which he gives the name thyroxin. It is an indol derivative, trihydrotriiodo-a-oxyindol-propionic acid, and Janney, who has clinical experience in the use of Kendall's preparation, considers that it is an hormone possessing the functions ascribed to the thyroid secretion. Kendall does not think that the iodine is of primary importance, and hence the omission of any reference to it in the name which he has given to his preparation.

#### *An Apparent Paradox.*

There is, then, considerable probability that the active principle of the thyroid is a breakdown product of protein which may be, but is not, necessarily iodised. Iodine, if present, has apparently no direct effect upon the activity of the internal secretion, and yet there is no doubt that when that activity is diminished it can often be restored to a certain extent by administration of iodides. Is there any explanation of the apparent paradox?

Jobling and Petersen have shown that unsaturated fatty acids have a powerful effect in inhibiting autolysis, but that in presence of iodine these acids on becoming saturated lose their inhibitory effect, so that the ferments causing autolysis are free to act. We have seen that the active principle of the thyroid is probably produced by the breakdown of protein in the gland—i.e., by autolysis. This process would, according to Jobling and Petersen, be facilitated by the presence of iodine in the gland, because the inhibitory effect of unsaturated fatty acids in the blood would be diminished or done away with owing to their saturation with iodine.

An inefficiency of the thyroid secretion might conceivably depend upon an excess of unsaturated fatty acids in the blood checking the autolysis by which the thyroid secretion is formed, and in such cases the administration of iodides would be effective by promoting the saturation of the acids. If the inefficiency of the thyroid were due to destruction or removal of part of the gland, the activity of the remainder might well be increased by iodides which are specifically taken up by the gland, and would there favour the characteristic autolysis by checking inhibition.

Possibly the curative action of iodides in tertiary syphilis may be explained by the thyroid effect of the drug in thus favouring an increase in the active secretion passed into the blood, and so facilitating the absorption of lowly organised tissues such as gummata, &c. The same would apply to the use of iodides in the treatment of enlarged lymphatic glands.

If the above premises are correct they suggest that tertiary syphilis might be at least as successfully treated with thyroid as with iodides; indeed, one might anticipate a quicker result, and, moreover, there would be no fear of iodism.

#### *Summary.*

The action of iodides in relieving a condition in which the thyroid secretion is deficient is due to two facts: (1) iodine is specifically absorbed by the gland; (2) the iodine in the gland in saturating the unsaturated fatty acids of the blood-supply favours the autolysis by which the active principle of the gland is produced.<sup>2</sup>

The efficacy of iodides in tertiary syphilis may be explained on these lines, and it is anticipated that tertiary syphilis may be successfully treated with thyroid.

<sup>2</sup> The usefulness of cod-liver oil in tuberculosis may be in part due to its high content of unsaturated fatty acids limiting to some extent the production of thyroid excretion, and so serving to prevent the absorption of the lowly organised tubercle tissue and the setting free of the bacillus.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### A CASE OF

#### NERVE TRANSPLANTATION.

By NEVILLE I. SPRIGGS, M.D. LOND., F.R.C.S. ENG.,

CAPTAIN, R.A.M.C. (T.); MEDICAL REFEREE TO MINISTRY OF PENSIONS; CITY POLICE SURGEON, ETC.

NERVE transplantation now being on its trial for war injuries of nerves, the following case, though only partially successful, is deemed worthy of record.

#### *The Case Described.*

Pte. S. was wounded in the left arm on Jan. 6th, 1916. There was a fracture of the humerus with clinically complete musculo-spiral paralysis. Several operations were needed before healing occurred, and then a large scar resulted very adherent to the bone. On Oct. 1st, 1917, the musculo-spiral nerve was exposed and found to be completely divided, with bulbs adherent to the bone. After excision of the bulbs the nerve ends could not be stretched to within an inch of each other. The external cutaneous nerve of the thigh was then searched for, and found with some difficulty as it was abnormally small. A length of two inches was removed, divided at its middle, and the two one-inch lengths so formed were stitched into the gap in the musculo-spiral side by side. A branch to the triceps, which was also implicated, was at the same time stitched in to the upper junction. The muscle was then stitched over the bone, between it and the bridged nerve, and the wound closed.

The wound healed well and the man was shortly after discharged from the Army and went to reside nearer his home in the north, where he was treated by electricity and massage as an out-patient. It was thought that his chance of recovering the function of the injured nerve was very small.

He was next seen by me on May 31st, 1918 (about eight months after the operation). Epicritic sensation, which had been lost on the outer side of the forearm owing to the low branching of the nerve, had then recovered. The wasting of the extensors and supinators was obviously less. There was slight but definite action both of the supinators and of the extensors of the wrist. There was no action of the extensors of the fingers and thumb. The grasp was good and the man was starting work. He was supplied with a "long cock-up" splint and told to wear it at night only.

#### *Result of Further Examination.*

Another examination has been made recently (May, 1919). The patient has been working since last seen. There is fair power in the supinators and in the wrist extensors, and there is slight power in the long extensors of thumb and fingers, so that one may hope that the man will still continue to improve.

The scar in the arm is still somewhat adherent to the bone, and probably to the repaired nerve also. I consider that had more attention been given to the excision and "toilet" of this scar a more complete and earlier recovery would have resulted.

I am indebted to Colonel C. J. Bond and to Dr. Annie C. Greenep for advice and help in this case.

### A CASE OF STOMACH AND BOWEL ATONY IN INFLUENZAL PNEUMONIA.

By NORMAN BRADLY, M.D.

IN THE LANCET of March 15th Mr. R. Eccles Smith has drawn attention to this condition in his paper on "Influenzal Intra-abdominal Catastrophes." The following case is recorded to show the value of pituitrin in this condition.

#### *Account of Case.*

Miss —, aged 21, was taken ill on March 4th and developed signs of pneumonia on the 9th. Toxæmia was profound, hæmoptysis was a recurring symptom, and severe cyanosis was constant, the administration of oxygen being almost continuous. On the 15th occasional vomiting of altered blood commenced and the pulse became markedly intermittent; on the 18th the temperature dropped to sub-normal, resp. 40-48, pulse 96; vomiting persisted and became

almost continuous; everything by mouth was stopped and replaced by salines per rectum; the vomiting became less frequent, but recurred at once on allowing anything by the mouth.

On the 20th her condition was desperate; temp. subnormal, pulse very intermittent and infrequent (50-60), resp. 40-48, deeply cyanosed, persistent vomiting, petechial hemorrhages under skin of chest; the liver dullness absent, upper part of abdomen distended, very restless and no sleep.

Six doses of pituitrin (0.5 c.cm. intramuscular and four-hourly) were given; in addition salines per rectum, fomentations, and gentle massage to abdomen. Forty-eight hours after the third injection of pituitrin the vomiting ceased, pulse became regular and more frequent (70-80). Respirations 20. The temperature had been subnormal for six days, a rise to 101° now occurred and gradually came down in a few days. The patient made an uninterrupted recovery. The condition was without doubt acute toxæmic dilatation of the stomach as seen in several post-mortems on these cases.

#### Remarks.

"Early stomach washing," as suggested by Mr. Eccles Smith, would no doubt have helped towards recovery, but was quite impossible on account of the extreme cyanosis; pituitrin and salines saved this patient. The irregular, and particularly infrequent, heart action as an additional sign of this condition may be worthy of note.

Crowborough, Sussex.

### A CASE OF LETHARGY.

By GRACE H. GIFFEN DUNDAS, F.R.C.S. IREL.,  
D.P.H. CAMB.

THE interest in this case lies partly in the question of diagnosis—was it a case of encephalitis lethargica?—and in the fact that the patient, being intelligent, was on convalescing able to tell something of her psychological state during her three weeks' cataleptic-like condition. I have permission from Dr. G. E. Oates, medical superintendent of the Ilford Isolation Hospital, to report the case.

#### Notes of Case.

*Previous history.*—Patient, aged 26, had erysipelas of face and scalp four years ago; very ill, high temperature, delirium, &c. She is nervous and quick-tempered. A few years ago she took up shorthand and typewriting, but was too "nervous" to continue, whereupon she confined herself to housework at home, at which she is very energetic. She was very nervous during air-raids, trembling violently. Three months before her present illness she had a great shock on hearing that a soldier to whom she had been engaged for years was killed. Her mother's illness (bronchitis) greatly worried her during the three months preceding her own illness.

*Present illness* began on Jan. 31st with a feeling of great restlessness. Patient had great difficulty in getting through her work that day. For a week previous to this she had headache and constipation. On Feb. 1st she remained in bed thinking she had "a nervous breakdown." That night she went into her sister's bedroom, not liking to be alone and not liking the dark. She got worse daily, and was admitted to the Ilford Isolation Hospital on Feb. 6th.

On admission patient lay supine without endeavouring to make the slightest movement. Limbs rigid. Elbows flexed and forearms lying across chest. Sweating profusely. Sordes on lips; mouth dry and dirty. Severe headache. Pupils reacted sluggishly to light. Partial ptosis of both lids. When asked to open her eyes she did so with difficulty. No squint, no diplopia, no evident loss of vision or paralysis of accommodation. Mask-like expression of face. Could neither raise her eyebrows nor frown; could not smile or close her eyelids firmly, or close her lips (upper teeth and part of gum exposed); could not use muscles of mastication. Understood all that was said. Answered with difficulty and in monosyllables; could phonate, but articulated badly. Could not depress lower jaw. It was not possible to ascertain if there was sensory paralysis of skin. No paralysis of taste. Thns there was no evident paralysis of third, fourth, and sixth nerves, but paralysis of motor branch of fifth, seventh, eleventh, and twelfth. Kernig's sign was absent; knee-jerks and Babinski's sign present. Arms and legs paralysed. Patient gave not the slightest indication of being aware that one was manipulating her. The back was red in places, she not having been moved during the seven days she had lain in bed. Menstruation present, had smelling discharge.

*Treatment.*—Patient was placed on a water bed and put on two-hourly milk feeds, occasionally varying the milk with Valentine's beef juice. Mouth toilet was attended to. Catheterisation and enemata were given when required.

*Subsequent history* until March 13th, when patient was discharged well. Temperature dropped to normal after two days; thereafter subnormal. Pulse gradually dropped to 80-90, respirations to 20. She slept deeply most of the time. Bed-sores occurred during the first week, but rapidly healed when she began to move a little. Retention of urine for the first few days, then incontinence. Constipation was extreme. Epsom salts, 1 drachm in each feed, had no result. Two large soap-and-water enemata with 1 ounce ol. ricini were retained. The gut was thereupon washed out, after which incontinence set in.

It was difficult to feed the patient, as she could not open her jaw. Fortunately, one or two teeth were absent. She could manage nothing but fluids for the first fortnight, after which she began gradually with solids. The first bite of bread and butter she tried had to be taken out of her mouth again, neither the power of mastication nor deglutition having returned.

Gross tremors of the limbs formed a prominent sign, especially marked if the patient tried to put out an effort to move the limb. Movement began three weeks after the beginning of the illness, first seen in the upper lip when asked to try to close her lips. Each day thereafter the orbicularis oris improved. The existing light did not allow of a series of photographs showing the daily improvement in frowning, smiling, &c. Movement in the arms next came back, the left being the last to recover. Then followed movement in neck, back, and lower limbs, the left leg being the last to recover. Strychnine was cautiously exhibited by the time the legs began to recover.

#### Sensations of Patient during Illness.

No emotional symptoms of any description accompanied convalescence. Patient was neither hilarious nor depressed. She voluntarily showed her daily progress in movements and expressed herself as grateful to the nurses for everything done for her.

She willingly told of her sensations during the three weeks when to all outward appearance she had no sensations. She thought she had lain five weeks without movement. There was an occasional hiatus in her mind as to the sequence of events, which may have been due, of course, to deep sleep. When awake she heard all that was said and would willingly have answered the questions I asked the nurse if she had had the power to. She was acutely aware of catheterisation, incontinences, &c. She had terrifying dreams usually, of someone trying to do her a bodily harm. Occasionally she had a distinct sense of well-being, but was unable to say if this sense followed on her gut being emptied or what.

She had lost sense of position and direction, having no idea of how her legs and her left arm were placed. Eyes and teeth seemed misplaced, her eyes up at the roots of her hair and her teeth several inches in front of her mouth. She resented her friends trying to keep her awake during the visiting hour. She resented them "chaffing" her, as she "could not chaff them back." I have only to add that the ward sister resented the friends expressing surprise at the cure nature had effected.

No case of encephalitis lethargica has been notified in this sanitary area. During the last 12 months two cases of poliomyelitis and one of cerebro-spinal fever were notified.

A fortnight after the patient's discharge from hospital—i.e., two months from the commencement of her illness—she was perfectly well with no untoward symptom, either mental or motor.

THE Dorset Education Committee has decided to appoint an additional assistant medical officer at a salary of £450 per annum.

HOUSING IN BELFAST.—A scheme has been evolved in Belfast (which, however, has still to be sanctioned by the Local Government Board), under which it is hoped that the first instalment of 1500 houses will be built within the next year at an estimated cost of £1,000,000. The Corporation have had several offers of sites for the new houses, so that no difficulty is likely to arise in this respect. But how will a workman pay a rental commensurate with the enormous cost of building houses? Will an increased city rate be acceptable to people who have suffered from the war if the great industries which require more houses contribute only in the same proportion? It is felt that the ship-building companies, who have earned much money during the war, might erect the houses themselves for their own operatives as part of their business. One thing is clear—owing to its increasing population, Belfast is badly in need of working-class houses.

## Reviews and Notices of Books.

*The Future of Medicine.* By Sir JAMES MACKENZIE, F.R.S., F.R.C.P., Consulting Physician to the London Hospital. London: Henry Frowde and Hodder and Stoughton. (Oxford Medical Publications.) 1919. Pp. 238. 8s. 6d.

EDUCATIONAL reform is an acknowledged need of the present day and the new Education Act is an earnest and well-thought-out attempt to satisfy that need in so far as general education goes. If a nation is not to drop behind in humanity's race its members must be educated, and in addition, they must be placed in the best position for profiting by the education supplied. A prime necessity for this desirable condition is health, for no sickly, ill-developed, or unhealthy learner can use the knowledge or means of knowledge supplied by his teacher to the best advantage. This being so, the next necessity is that that portion of the community in whose hands lies the preservation of the nation's health—namely, the medical profession—should learn how to carry out the great work entrusted to them in the best and most profitable manner. This is the simple message from Sir James Mackenzie to his fellow-students contained in this book. Over and over again it has been said in different ways and with different arguments, so that no one, medical or lay, will be found to dispute the proposition; there is plenty of room for its enthusiastic support, and never has there been provided finer advocacy than that of Sir James Mackenzie.

Despite all the advances which have been made in medical science during the last 50 years, no one realises more keenly than do medical men themselves, that our knowledge of disease practically only begins when the patient is already more or less damaged, and that though the ideal of medicine is "*pricipiis obsta*," yet only in very few instances are we able to carry out this precept. Teaching is at fault, teachers are at fault, examinations are at fault, and consequently practice is hampered; even while in this country our tests are fair, our examinations standardised, and our instructors in the main keen and often distinguished, if poorly-paid men. Sir James Mackenzie treats in admirably simple language, and with a wealth of illustration, the position outlined above, and is able to do so from a strong position, for he has personally triumphed over the difficulties which lie ahead of the reformer, and has vastly improved medical practice by his personal teaching. His thesis includes three heads, which seem obvious to absurdity and yet are apparently but little realised. Shortly, they are as follows: 1. If a problem is to be solved, the nature of the problem and its difficulties should first be comprehended. 2. Disease is only made manifest by the symptoms which it produces, and to get a thorough understanding of disease we must recognise the symptoms not merely by detecting their presence, but by understanding the mechanism of their production and their bearing on the health of the patient. 3. He who conducts the investigation should have had the opportunity of seeing disease in all its phases, and of observing the various symptoms which it produces. Allow these premises, and it follows that only one class of individual has the opportunity for acquiring the knowledge, and that is the class of the general practitioner. This position leads Sir James Mackenzie to a chapter upon medical education wherein he puts his finger upon one of the weak points in the present system of medical education—namely, its divorce from the work of the general practitioner. The average teacher either has no experience of the difficulties which the majority of his pupils will meet with in their life's work, or if he has had any experience of such difficulties in his own training he seems to have forgotten them.

It must have occurred to many persons of intelligence—both teachers and taught—that books written with the idea of instruction might well be written not by a master of his subject alone, but in collaboration with an intelligent learner. The master might write a chapter and then hand it over to the learner for comment and the latter could then, when he came to a passage which puzzled him, say "What do you mean when you say this?" Written after this manner, a book would gain infinitely in value as an educational agency, but the teaching in hospitals, which are at present

the only schools of medicine, cannot be conducted after the same model. The value of the old apprenticeship system, the return of which we are not advocating, was that it offered personal communication between the learner and a teacher who was living and working under the very difficulties which the learner would one day have to deal with. At the present day, says Sir James Mackenzie, the student is instructed by a number of teachers not one of whom has had any experience of the life he is to lead as a general practitioner; and, moreover, the general practitioner, who has sometimes suffered from a defective education, is never consulted on educational matters. In the system of apprenticeship, however, there would never be any guarantee that the master was able, or had the leisure, to teach the pupil properly, so that the system can find no place in a standardised curriculum.

We have said enough to indicate the line of argument which Sir James Mackenzie pursues, and we think that his suggestion that in every school of medicine there should be one or more teachers who have passed through 10 to 20 years of general practice is an admirable one. We can see no better method of supplying teachers who have a knowledge at first hand of what ought to be taught.

*Text-book of Ophthalmology.* By Hofrath ERNST FUCHS, former Professor of Ophthalmology in the University of Vienna. Authorised translation from the twelfth German edition, by ALEXANDER DUANE, M.D. Sixth edition. London and Philadelphia: J. B. Lippincott Company. Pp. 1067. 30s.

THIS text-book is too well known to need recommendation. The present edition is nearly a reprint of the fifth which appeared two years ago, but the changes between the fifth and earlier editions were numerous and important. For these Professor Duane is almost wholly responsible. No new German edition has appeared for some years, and the book, though based on Fuchs's original text, tends to become more and more the work of the American translator. Its composite nature remains, and in most parts additions and alterations are indicated by the use of brackets and the translator's initial D. Some parts are rewritten; for instance, the chapter on disturbances of motility, a subject which the translator has made peculiarly his own. All this tends to increase the bulk of the volume. And yet in parts it still needs to be brought up to date. In the chapter on Glaucoma, for example, we find a good deal about the older theories of its pathology, but no sufficient directions for taking the visual fields, or of their importance in early diagnosis. Again, the older theories of colour blindness are explained at considerable length, but the newer ones nearly ignored. For the beginner we should recommend a smaller text-book, but as a book of reference and for the advanced student, the work of Fuchs will still be deservedly popular. The chapter on Diseases of the Cornea and the sections on Pupillary Reactions are hard to beat. Therefore, we say that for anyone who has time to study the book in its entirety it will doubtless be of great value, but he will soon discover that, in a subject which is alive, no single text-book can possibly be sufficient for all that he will need. Especially in the chapter on Operations, more references would be useful, so that the full description of any particular operation that the operator is at all likely to require could be easily found at a library. The same principle might perhaps be applied to the rarer diseases and to important observations relating to the commoner ones.

*Auto-Erotic Phenomena in Adolescence.* By K. MENZIES. With a foreword by Dr. ERNEST JONES. London: H. K. Lewis and Co., Ltd. 1919. Pp. vii. + 88. 4s. 6d.

THERE is so much nonsense written on the subject of masturbation that such an analytical study of the psychology and psycho-pathology of onanism as has been prepared in this small volume has become an unpleasant necessity. Mr. Menzies has read widely in his subject and writes as a psychologist. The mental conflict engendered by false conceptions of this habit is considered to be the most serious aspect of the problem. Whether it is necessary to invoke the aid of psycho-analysis in treatment of the numerous sufferers is a question the reader will answer according to his belief in this method of

psychotherapy. When once the condition itself is properly understood, a little common sense and a rational education of the young may well make the somewhat painful and cumbersome efforts of the skilled psycho-analyst unnecessary. But whatever we think of Mr. Mcnzies's views of treatment, or of his ethical considerations, we cannot but be grateful that he has handled his subject in a sane way. In the result he has achieved nothing new, but he has made available in a small compass the experience and conclusions of many writers whose opinions are worth knowing.

*A Short Practice of Medicine.* By ROBERT A. FLEMING, M.A., M.D., F.R.C.P.E., F.R.S.E., Lecturer on Practice of Medicine, School of the Royal Colleges, Edinburgh; Senior Lecturer on Clinical Medicine, Edinburgh University; Physician, Royal Infirmary, Edinburgh. Third edition. London: J. and A. Churchill. 1919. Pp. 676. 21s.

THE purpose of this manual is to provide students attending lectures on medicine with a general synopsis of that subject. The author suggests that its use will free the teacher from dictating, year in and year out, statements which can be mastered as well, if not better, from a text-book. It is perhaps not surprising that the index of a text-book on the practice of medicine contains no reference to acidosis or vagotonia, but when one looks in vain for colon bacilluria or encephalitis lethargica one is forced to the conclusion that the writer either has not taken the full advantage which a new edition offers for the inclusion of new material, or considers such subjects more suited to oral instruction. However this may be, the opportunity has been taken to rewrite and bring up to date the descriptions of many diseases, and various medical diseases met with during the war, such as trench fever and trench nephritis, have received recognition. The book is arranged on the usual plan adopted in works of systematic medicine. We notice that rickets, scurvy, and beri-beri are classed together as diseases due to faulty nutrition. Rheumatoid arthritis is not very clearly distinguished from osteo-arthritis and is found, with osteomalacia, hypertrophic pulmonary osteoarthropathy, osteitis deformans, and achondroplasia, under diseases of bones and joints. No mention is made, we observe, of the association between diabetes insipidus and morbid change in the pituitary body, but the writer of a synopsis has to confine his work within definite limits, so that some omissions become imperative, the author being the arbiter. The old anatomical terminology is used throughout the book and we think the author is to be commended on its retention; for the sake of those who are accustomed to the international nomenclature a table of such equivalent terms in the two systems as have been made use of in the text is provided. Several new illustrations have been added and these now number 64, nearly half of them occurring in the section devoted to diseases of the nervous system.

The book provides a very fair summary of the current views on medicine, but we are inclined to think it is likely to prove of greater use to students than to practitioners.

*A Text-book of Practical Therapeutics.* By HOBART AMORY HARE, M.D., B.Sc., Professor of Therapeutics, Materia Medica, and Diagnosis in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital. Seventeenth edition. London: Henry Kimpton. 1919. Pp. 1024. 28s.

This work thoroughly justifies its title of "practical therapeutics with especial reference to the application of remedial measures to disease and their employment upon a practical basis." Although there is of necessity a certain amount of theoretical discussion the practical element is never lost sight of. Great care has been taken to bring this edition fully up to date, and so many alterations and additions have been found necessary that a large part of it has been reset in new type. Though we are dealing with a seventeenth edition, it is not an old treatise.

Most of the book is taken up with a consideration of "drugs." Under this heading the various preparations used in the practice of medicine are fully discussed. A uniform method is adopted throughout. A description is first given of the drug, then its physiological action is explained at sufficient length to enable the reader to appreciate fully its effect upon the various systems of the body. Next, its

therapeutic use is considered, and the indications for its employment. The mode of administration is also explained, and when necessary the symptoms of poisoning are also given. In the preface Professor Hare remarks that "many important drugs heretofore made in Germany, or under German patents, are now made in this country and have been given names whereby they may be properly designated." It may be that practitioners will not at first recognise these names; for instance, the word arsenamine is adopted for salvarsan (although in the full description which follows the name salvarsan is retained throughout); procaine is substituted for novocaine, and barbital for veronal.

Experience during the war has increased the knowledge in relation to shock, and has emphasised the need of careful methods of intravenous injection or of direct transfusion; therefore the technique of these procedures is fully and clearly described. The use of Dakin's fluid and dichloramine-T by Carrel's methods is also discussed. We would draw attention to the valuable remarks on chloroform and the method of its administration. The section of the book dealing with the treatment of various diseases will be appreciated by practitioners, as will also be the index of diseases and remedies.

We believe that this work will particularly appeal to those in general practice, who will find it a useful work of reference; the material contained in it is essentially practical, and owing to the general arrangement of the book the information required can be easily found.

*Anti-malaria Work in Macedonia.* By W. G. WILLOUGHBY, M.D., and LOUIS CASSIDY, M.B. With 14 plates. London: H. K. Lewis and Co. 1918. Pp. x. + 68. 3s. 6d. net.

THE authors in their preface to this little book of about 50 pages of text expressly state that it is "not intended as a scientific work," after which we cannot expect the subject-matter to be treated in a scientific way, though the authors' efforts are commendable. But we must express our sorrow that it should be necessary to issue a book of this kind for the use, apparently, of medical officers. If we may read between the lines, the authors appear to have had to struggle against "regulations" and, indeed, to put it bluntly, against ignorance, for on p. 65 they say coöperation in anti-malarial measures is far more satisfactory when its basis is intellectual. We see no indication that the authors lived in an atmosphere of research. What anopheline or anophelines were the carriers, what percentage of these were infected, what was the infection rate amongst the indigenous population and the troops, what were the breeding-places of the transmitting species, are not stated. It is information such as only specially trained medical men could give. We believe that an anti-mosquito campaign can only be scientifically and economically carried out if these factors are known, and that it is unscientific to proceed in the dark and take measures against all anophelines. Suppose, for instance, that the main carrier is a species restricted in numbers with restricted breeding-places, a supposition that in certain cases actually agrees with the facts, then it is good policy, especially where labour is a difficult question or money is scarce, to proceed against this species first.

This book, then, gives the impression that research was not in progress in the field of malaria operations in question. The authors, however, believe that the actual anti-malaria operations were successful, though the data for forming an independent opinion are not given.

*Life and Its Maintenance: A Symposium of Biological Problems of the Day.* London, Glasgow, and Bombay: Blackie and Sons, Ltd. 1919. Pp. 297. 5s.

*Lectures on Sex and Heredity, delivered in Glasgow, 1917-1918.* By F. O. BOWER, J. GRAHAM KERR, and W. E. AGAR. London: Macmillan and Co., Ltd. 1919. Pp. 120. 5s.

THE first of these books is a volume of 15 lectures which were delivered to a mixed audience at University College, London, during the spring of 1918 and which were designed to deal with the vital war problems such as the supply, nutritional value, and production of food, the physiological aspects of flying, the anaerobic treatment of wounds, and industrial efficiency and fatigue, the lecturers being selected from professorial chairs of the universities of the country or

from important institutions for research such as the Lister Institute of Preventive Medicine. Although the lectures were called forth by the exigencies of war, they cannot but have an important bearing in times of peace, more especially during the reconstruction period, in the throes of which we now are. The Problem of Food, by Professor William Bayliss, and War Bread and its Constituents, by Professor F. G. Hopkins, discuss important matters which expanding populations and economic needs make vital, while Vitamines, by Miss E. Margaret Hume, is a subject equally urgent in its bearings. Professor Cushny's lecture on Alcohol and other Beverages in War Time, while not encroaching upon the controversy which is engaging the attention of America at the present moment, and which in the near future may react upon our own country, inquires how far beer, and incidentally domestic beverages, may be regarded as food. The Physiological Aspects of Flying, by Lieutenant-Colonel Martin Flack, will be read with interest now that the commercial possibilities of aviation are something more than a dream, and the subjects of Efficiency and Fatigue and Fresh Air and Efficiency, respectively dealt with by Dr. H. M. Vernon and Professor H. R. Kenwood, are matters with which the new Ministry of Health will have much to do.

The lectures on Sex and Heredity deal with a somewhat abstruse subject in simple language. Scientific terms are freely introduced, but their definition is repeated in paraphrase again and again as occasion suggests, while abundant illustrations and a glossary further help the reader. No indication is given as to where or to what audience in Glasgow the lectures were delivered, but presumably they were given in the University, as two of the three lecturers are respectively Regius professors of botany and zoology there. The aim is to give the leading facts in relation to sex in animals and plants, together with suggestions bearing on the use and effect of sexual propagation, and this has been abundantly fulfilled. The lectures make a simple and admirable introduction to such subjects as race regeneration and eugenics, which, after the devastations of war, are likely to occupy the minds of thoughtful people for many years to come.

*The Urethroscope in Diagnosis and Treatment of Urethritis.*

By Major N. P. L. LUMB, O.B.E., R.A.M.C. (T.C.). London: John Bale, Sons, and Danielsson, Ltd. 1919. Pp. 52. 10s. 6d.

THIS book performs two useful tasks: First, it emphasises the necessity for the use of the urethroscope in all cases of urethritis; and, secondly, it gives to the practitioner some idea as to what he may expect to find by looking through the instrument. The illustrations, which are all coloured, are quite good, although perhaps a little diagrammatic in places, but suffer from the disadvantage that the references in the text necessitate a repeated turning over of pages. Still, this is a minor point. The advantages of the Wyndham Powell aero-urethroscope are wisely taken into account. The author does not pretend that the book is complete. It is a useful contribution in that it depicts in the illustrations the effect of treatment on the pathological condition found in cases of urethritis.

*Ten Lectures on Field Sanitation.* By C. B. MOSS-BLUNDELL, M.D., D.P.H.; Captain, R.A.M.C. (T.F.). London, Aldershot, and Portsmouth: Gale and Polden. 1919. Pp. 134. 5s.

THIS book, which has a commendatory introduction by Major-General Gerald Cree, contains a series of lectures delivered by the author at a school of sanitation in France of which he was the commandant, and their object is to teach the practical side of sanitation in the field. The lectures discuss the general principles which underlie the sanitary problem in active service, the details of the syllabus embracing the dangers from horse manure and the menace of flies, the disposal of excreta and refuse, the method of dealing with water-supplies, food, and disinfection. Diagrams are freely used in elucidation of the text. The author, who is county medical officer of health for Huntingdonshire, has brought to the compilation of the lectures a wide experience of sanitary matters gained both before and during the war, and his treatment of the subject will prove valuable, not only to R.A.M.C. officers, but also to officers in other branches of the service.

## JOURNALS.

In the *Military Surgeon* for July, Colonel B. K. Ashford completes a lecture on Field Hospitals, in which he tells the newly arriving officers of the American Medical Corps what they should aim at in providing accommodation for their wounded. The wounded sent back from the advanced dressing station are examined at the field ambulance and there sorted as to their next destinations. This sorting or, as the French call it, triage, must never be done except at a place where there is a chance of dealing with grave emergencies. Therefore, he says, in action the field ambulance must be able to deal with cases of hæmorrhage, shock, severe compound fractures, chest and abdominal cases, all untransportable, and consequently it must be strengthened in time of action by an advanced surgical section and a radiologist. He discusses the French and English field hospitals as he has seen them, and notes how field ambulances are in turn taken out of the line and made to do duty as gas hospitals, rest stations, hospitals for medical, infectious, or scabies cases. He gives high praise to the British for cleanliness. Never, he says, has he smelt fæces in the British lines; their latrines may never be near their kitchens, which, like the cooks, are spotless. Many trades were represented about the hospitals of rest—tailors, cobblers, saddlers. Much, too, was done for the comfort of the men, who had a gymnasium, library, entertainments, theatricals, and plenty of open air, so that 80 per cent. go back to their units. Colonel Ashford expresses a high opinion of the French Bessoneau tent, of their mobile surgical units, and of their hospitals for gassed cases. He notices that in one attack only some 15 of those supposed gassed were really so; the others were mentally and physically exhausted, but they, too, required treatment. In the same issue Major G. A. Soper recounts the history of the notorious "Typhoid Mary," who in 18 years is believed to have originated ten outbreaks of enteric while acting as a cook in various circumstances.

*Journal of the East Africa and Uganda Natural History Society.* July, 1919. London: Longmans, Green, and Co. 5s. 4d. to non-members.—This number contains two papers of medical interest, Major C. E. Southon's description of plague and its history, and Mr. R. E. Montgomery's story of insects in relation to the diseases of stock. Dr. J. H. H. Pirie has a note on the Ebnrrn steam jets (natural emanations of hot aqueous vapour from the ground), some of which have been used for obtaining a water-supply, the steam being condensed on metal plates. Mr. V. G. L. van Someren sends some notes on East African birds and on the European crane, and Dr. R. van Someren is responsible for a group-picture of sacred ibis, cormorants, and stone curlew on an island on the Victoria Nyanza. A contributor asks whether albinism is only found among males in South Africa, as in the half a dozen cases he has met with he has never seen an albino woman, and another contributor describes an albino child at Malende, south-east of the Taita Hills; this boy was about 10 years of age, with skin and hair quite white. The eyes were of a watery blue, and he complained of the bright sunlight. There were marks on his face resembling very large freckles, and his lips were badly blistered by the sun. The boy seemed intelligent, and his father, mother, and two sisters were all quite black.

## SOCIÉTÉ DE BIOLOGIE, PARIS.

At a meeting of this society held on July 26th the following papers were read:—

Dnbois.—Pseudo-cellules Symbiotiques Anaérobies et Pathogènes.

On peut obtenir des pseudo-cellules pathogènes et même des pseudo-tissus parenchymateux avec des photobactéries, mais cela ne peut pas que les cellules animales ou végétales en général et en particulier les cellules pathogènes, soient formées par des agglomérations microbiennes.

Le Moignic et Sezary.—Lésions Pulmonaires Consécutives aux Injections Intraveineuses d'Huiles Végétales.

Des injections intra-veineuses uniques ou rarement répétées, d'une dose d'huile d'olive variant de 0,03 c.cm. à 0,2 c.cm. par kilogramme d'animal, ne déterminent que des altérations légères du poulmon. Des injections répétées 15 à 30 fois provoquent une sclérose interstitielle diffuse, enserrant les alvéoles, diminuant notablement le champ de l'hématose. L'incorporation à l'huile de substances médicamenteuses produit des lésions graves de broncho-pneumonie nécrotique. L'huile camphrée seule est bien tolérée expérimentalement.

Le Moignic et Norero.—Recherches sur la Distribution des Huiles Injectées dans la Trachée.

On injecte à un gros chien par piqûre de la trachée de petites quantités d'huile colorée par des substances peu ou non diffusibles. Autopsie après 24 heures. L'huile ne se départit pas en définitive dans tout le parenchyme pulmonaire, elle se rend surtout à des lobules des parties inférieures du poulmon; il est rare qu'elle se distribue abondamment au lobe supérieur.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 6, 1919.

## The Future of Liquor Control.

IN view of the approaching extinction of the Liquor Control Board and the proposed establishment, in its place, of a permanent authority directly responsible to Parliament, special interest attaches to the speech delivered by Lord D'ABERNON at Carlisle last week dealing with the future of drink policy in this country. Lord D'ABERNON was in the position of being able to point to a record of successful administration in a difficult sphere where generations of reformers and legislators have failed. At a time when public opinion is showing itself much more alive to the shortcomings than to the achievements of the State in the many unusual activities thrust upon it by the war, the Liquor Control Board stands out as a department of the Government whose work during the national emergency has won general recognition not merely for its accomplishment of the immediate purpose for which it was created, but also as having made a contribution of permanent value to the solution of a notoriously difficult social problem. We know all the directions from which the Liquor Control Board has been criticised, but the fact emerges that when something had to be done the Board did it successfully. And readers of Lord D'ABERNON'S speech will not be at a loss to find the explanation of this success.

The history of liquor legislation in the past has been marked by an entire blindness to the fact that the problem of alcoholism is in a very large and important measure a problem of pharmacology. Lord D'ABERNON, with the intuition of statesmanship, and with the even more useful quality of being able to trust scientific advice, grasped this fundamental and neglected truth. The potential efficacy of legislation against intemperance depends largely on the fact that the conditions which physiology indicates as necessary to prevent the injurious action of alcohol appear generally to be such as can be adequately secured by legislation or regulative measures. When, for example, the physiologist teaches that alcohol gets into the blood very quickly and gets out of it very slowly, and that its persistent presence in the system is the main cause of chronic alcoholic poisoning, the obvious precaution is the quite feasible one of providing against public-houses being open for long continuous periods. Similarly, when it is shown that an alcoholic drink taken in dilution is very much less injurious than the same dose taken in an unduly concentrated form, the obvious precaution is to provide against the sale of alcoholic beverages at excessive strengths, and to bring about effective dilution by encouraging the consumption of alcohol with meals instead of offering dangerous facilities for drinking on an empty stomach. The regulation of the liquor trade in accordance with these principles has brought about a reduction of intemperance and a consequent improvement in national health and efficiency which a very few years ago would have appeared impossible of attainment by any practicable measures of reform, and the accompanying interference with the liberty of the subject cannot

be described as a counterbalancing mischief. The lesson which Lord D'ABERNON draws from this experience is that the pre-war prevalence of alcoholism in this country was primarily attributable to the absence of any rational system of liquor legislation, and that, should relapse to these pre-war evils occur, it will similarly be the fault of the legislation. In this matter the immediate responsibility of the State is clear and definite: under the existing licensing system, the retailers of liquor are not traders in the ordinary sense of the term, they enjoy a monopoly granted to them by the State, and it is the duty of the State to regulate in the public interest the conditions under which that monopoly is exercised. In the United States the abuse of their privileges by the liquor traders has led the legislature to adopt the extreme policy of absolute prohibition. In this country the experience of the Control Board has shown that more moderate methods may be at least as effectual in safeguarding public health and order, while they have the additional advantage—of no small account at the present moment—that they do not involve the sacrifice of a source of State revenue which may be capable of such development as should make it second only to the income-tax in productiveness.
